The exhibition celebrates Bristol Museum's acquisition and curation of these three major finds. But it also narrates the museum's key role in the history of research on marine reptiles, and laments the destruction, in an air raid in 1940, of the original collection of marine reptiles, the finest in Britain outside London<sup>12,13</sup>. It was here during the 1820s that W. D. Conybeare and H. T. De la Beche carried out the first accurate assessments of ichthyosaurs and plesiosaurs, interpreting them as links in the "great chain of being" between fish and reptiles<sup>14</sup>. These marine reptiles helped to popularize palaeontology, and — ironically — to give the impetus leading to the replacement of the paradigm of the great chain by darwinian evolution. Now the cycle is complete and the marine reptiles are once again receiving well-deserved attention. □

animal, from Somerset, is distinguished by a long, protruding upper jaw, presumably for slashing through schools of prey too small to catch individually.

The Westbury pliosaur is a fortunate exception to the destruction of fossils by modern quarry machinery before they are even spotted<sup>4</sup>. The 1.6-m-long skull of *Liopleurodon macromerus* is exceptionally well preserved, and comes from an animal perhaps 6 to 7 m long. The robust jaws, strong pointed teeth with cutting keels, and wide gape indicate a predator which killed and tore apart any prey which it could catch<sup>5,6</sup>.

The ecological diversity of ancient seas must have been very great to have supported all these large, carnivorous sea-dragons simultaneously. The next task is to sort out the adaptations of each in order to gain a better appreciation of their ecological niches. One approach is to use tooth form and wear, supplemented by stomach contents, to assess dietary specialization<sup>6</sup>. Another is to compare locomotor adaptations<sup>7–10</sup>: the fish-shaped ichthyosaurs and the compact, short-necked plesiosaurs were probably fast pursuit predators, while the longer-necked plesiosaurs may have used their long necks to ambush smaller prey while cruising. Despite the presumed speed of ichthyosaurs and plesiosaurs, they were probably slow when compared with modern forms such as toothed whales<sup>9–11</sup>. The evolution

# Painting by resonance

Chris Scarre

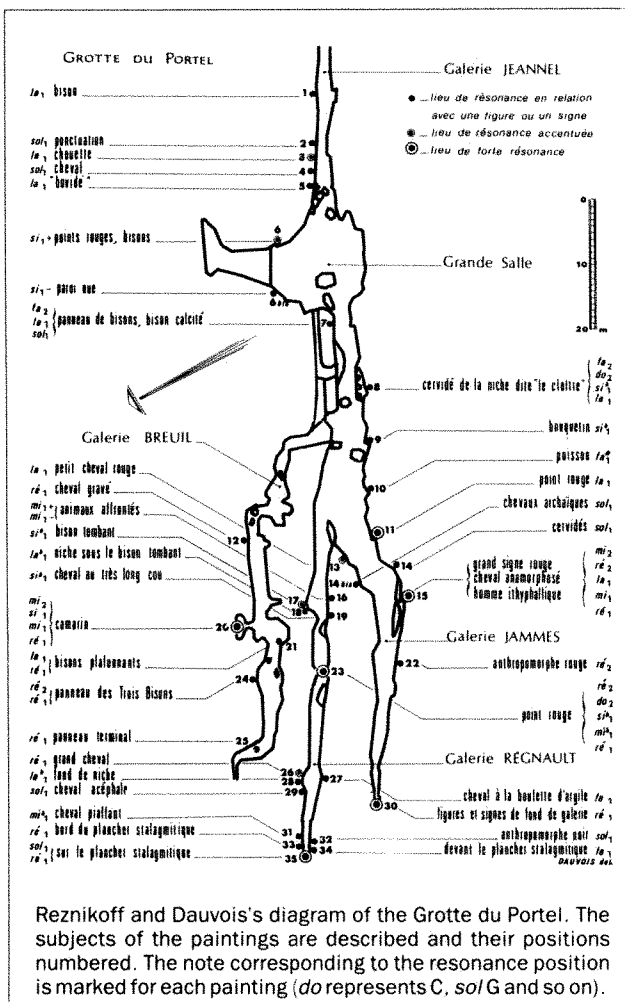

DID the painted caves of western Europe once resound to the music of Palaeolithic chants? Such is the thesis put forward by Iégor Reznikoff and Michel Dauvois in the latest issue of the *Bulletin de la Société Préhistorique Française* (85, 238-246; 1988). The authors have studied three caves in the Ariège department at the foot of the French Pyrenees. Their results suggest that the acoustics of the caves played a significant part in determining where the paintings were located, and this observation leads directly to the supposition that music or chants were important elements in cave ceremonies around 20,000 years ago.

Reznikoff and Dauvois rely on the fact that in certain places ("points of resonance") the caves resonate in response to particular notes. They proceeded slowly through the cave using their voices to produce a series of notes spanning almost three octaves, from C<sub>1</sub> to G<sub>3</sub>. They extended the range of notes for a further two octaves by harmonics and whistling. Where there was a resonance response, they recorded the location and the particular note eliciting the response. They used these observations to draw up a resonance map of the cave (see figure).

The resonance of the caves is not in itself surprising, but the significance of the study becomes apparent when the authors compare their points of resonance with the location of cave paintings. They draw three main conclusions. First, most of the cave paintings are at or within 1 metre of points of resonance. The Grande Salle at Portel, for example, which gave no resonance response, also has relatively few paintings. Second, most of the points of resonance correspond to locations with cave paintings. Indeed, the best points of resonance are always marked in this way. Finally, the authors claim that the location of some of the paintings can be explained only by the resonance of that particular location. A good example is number 23 at Portel (see figure), where a particularly effective

point of resonance is marked by red painted dots, as there is not enough room for a full painted figure.

Reznikoff and Dauvois remark from their own experience on the impressive effect of cave resonance, which would have been all the more striking in the flickering half-light of the simple lamps or tapers used by the original artists. Drums, flutes and whistles may have been used in cave rituals — bone flutes have been found at several Palaeolithic sites in Europe of roughly the same age as the paintings. The potential of cave resonance

would, however, be elicited only by the much greater range of the human voice. The image of the cave artists chanting incantations in front of their paintings may not be too fanciful. Reconstructing prehistoric sounds is inevitably a risky and ambitious venture, but this study is of particular value in drawing new attention to the likely importance of music and singing in the rituals of our early ancestors. □

# Time out of mind

LIKE many busy people, Daedalus often wishes there were more hours in the day. Indeed, he has given serious thought to slowing down the rotation of the Earth, but still cannot think of a suitable dumping-ground for the surplus angular momentum. Instead, he is exploring the possibility of speeding up the human internal clock. In most people its free-running period is about 25 hours, entrained with more or less reluctance to the 24-hour day by the pitiless light of morning. But those infuriating eager-beavers who snap into action at the crack of dawn presumably have a cycle of less than 24 hours, and so adjust to the natural day with some phase-lead.

Many other creatures also have an inbuilt circadian rhythm. It seems to be genetically determined; hamsters and fruitflies sometimes occur in mutated forms with a different circadian period, or even with none at all. These mutations seem to work by altering the output of some time-regulator protein. If the same mechanism works in man, then the human internal clock could be neatly adjusted by altering the output of this protein. So DREADCO's pharmacologists are trying to develop a drug which either blocks the receptors for the timing protein, or inhibits or facilitates its production. In the current state of knowledge, this has to be a hit-and-miss business; but the hormone melatonin and the benzodiazepine tranquilizers, both of which affect the biological clock, seem a good place to start. Serum analysis of volunteer sluggards and human dynamos may also be revealing.

DREADCO's Regulator® tablets will bring wonderful harmony to all our lives. Those who (like Daedalus) find that morning comes too soon, will shorten their cycle by cautious doses of the appropriate Regulator until they are in perfect tune with the clock. Their short-cycle brethren will lengthen their subjective day to make the most of the evening. But Daedalus is most intrigued by the possibility of a special Regulator which, like the *per<sup>0</sup>* mutation in fruitflies, does not merely alter the circadian rhythm but actually abolishes it. Acyclic individuals will live a very unusual life. They will show no particular tendency to go to sleep; once asleep, however, they will show no particular tendency to wake up. Having no time-sense, they will never be bored; and they will only eat when actually hungry. Acyclic workers will take over all the continuous industrial processes which are currently manned imperfectly, and often dangerously, in shifts. They will severely test theories about the importance of sleep and dreams to human mental functioning. And if our lifespan is indeed counted off in periods of the circadian rhythm, they should live forever.

David Jones

# Effect of N<sub>2</sub> on superconductors

SIR—Matthews *et al.*<sup>1</sup> reported that the superconducting transition temperature ( $T_c$ ) of YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7</sub> ( $y \approx 7$ ) ceramic can be increased by exposure to cold gas. Exposure to nitrogen raised  $T_c$  by nearly 40 K. Sarma *et al.*<sup>2</sup>, however, performed experiments which led them to suggest that this observation could be explained by condensation of nitrogen gas in the porous ceramic, but Matthews and colleagues have supported their own interpretation by further experiment<sup>3,4</sup>. It is clearly important to establish whether or not the transition temperature of a superconducting ceramic can indeed be raised by such a simple procedure. In an independent investigation, we find no effect of cold nitrogen gas on  $T_c$ .

Superconducting transition of encapsulated and unencapsulated half-disks of YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7</sub> ceramic.

Our samples were disks of YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7</sub> ceramic, about 10 mm in diameter and 2 mm thick, supplied by N. Alford of ICI Advanced Materials. Superconductivity was detected by measurements of a.c. susceptibility. The temperature of the specimen-holder was varied by means of the metal-cylinder apparatus described elsewhere<sup>5</sup>, in which the specimen holder is held in a vertical column of cold nitrogen gas along which a temperature gradient is established. The temperature of the specimen holder can be varied by raising it to the appropriate height, and was measured using a silicon diode thermometer. When measuring  $T_c$ , the temperature was varied at less than 1 K min<sup>-1</sup>, a rate for which preliminary experiments showed a negligible temperature difference between the specimen and the thermometer. The induction coils were separated from the specimen by a few millimetres so that the surfaces of the latter were exposed to the cold nitrogen gas.

The changes in  $T_c$  reported in refs 1, 3 and 4 are so large (up to 40 K) that they should be easy to observe. Nevertheless, to ensure that any change would be detected, we cut one of the specimen disks in half along a diameter. One half was encapsulated, by means of a chemical-dip treatment, and the other was left untreated. The two halves were placed together

between the coils. If the nitrogen gas does indeed alter  $T_c$ , we should observe two transitions, one in the encapsulated half at the original transition temperature and one in the unencapsulated half at a higher temperature. The a.c. susceptibility of a pair of specimens, as they were first cooled from room temperature to 80 K, is shown in the figure. The small step in the voltage drop shows that the two halves have very slightly different transition temperatures ( $\sim 0.3$  K) and that our apparatus would detect any change in the  $T_c$  of the unencapsulated specimen.

Experiments were performed on six samples, four of 15% porosity and two of less than 2% porosity. Specimens were exposed to nitrogen gas at 80 K for up to 43 hours, the transition temperature being measured at intervals of a few hours. No change in  $T_c$  was observed for any specimen; the variation in a.c. susceptibility with temperature after exposure to cold nitrogen gas was no different to that observed during the initial cooling.

Thus we have not been able to reproduce the increase in  $T_c$  observed in refs 1, 3 and 4, nor indeed did we detect any change at all in  $T_c$  resulting from exposure to cold nitrogen gas. Moreover, although many other experiments must have involved exposure of ceramics to cold gas for long periods, there is, as far as we are aware, no report of a resulting increase in  $T_c$ . We cannot explain the results of Matthews, Taylor and co-workers; there may be a flaw in their experimental method, possibly of the kind suggested by Sarma *et al.*<sup>2</sup>, or perhaps their samples are not typical of YBaCuO ceramics.

## Antigen receptor tail clue

SIR—I wish to draw attention to an amino-acid motif present in the cytoplasmic tails of several protein components of the antigen receptors on T cells and B cells<sup>1,2</sup>, as well as the immunoglobulin E (IgE) receptor (FcRI) on mast cells<sup>3</sup>. These receptors show similar structural and functional properties; they consist of several different transmembrane proteins which upon cross-linking generate a signal resulting in cell activation.

As shown in the figure, the motif is found in the CD3- $\gamma$ , - $\delta$  and - $\zeta$  components of the T-cell receptor (but not the CD3- $\epsilon$  or TcR- $\alpha$  or - $\beta$ , components); in the MB1 component of the immunoglobulin M antigen receptor on B cells and on the FcRI- $\beta$  and - $\gamma$  components of the receptor for IgE on mast cells (but not the FcRI- $\alpha$  component). When the con-

sensus sequence motif derived from these components was used to search the NBRF protein databank for related protein, two were identified: a B-cell-specific membrane protein, B29, of unknown function<sup>4</sup> and the envelope protein, gp30, of bovine leukaemia virus (BLV)<sup>5,6</sup>.

The first two specified amino acids of the motif are the negatively charged aspartic acid (D) or glutamic acid (E); the third and fifth are tyrosine (Y); and the fourth and sixth are leucine (L) or isoleucine (I). All six are located with a precise spacing between each other, and would lie on the same side of an  $\alpha$ -helical barrel if the cytoplasmic sequence formed an  $\alpha$ -helix. On cross-linking of receptor, the conserved amino acids from several chains may come together to form a binding site for the putative proteins that generate the

## Solar oscillation

SIR—Gough discusses the recent helioseismic evidence for solar-cycle variations in the global solar aspherical structure. But he does not mention that the variable, even, helioseismic-splitting coefficients; the solar-limb temperature measurements; and the solar-constant data together yield a consistent interpretation of solar asphericity. Gough speculates that the splitting coefficients are directly related to sunspot number, and using a Legendre polynomial decomposition of the surface distribution of sunspots, makes a prediction<sup>1</sup>. It is not obvious, however, that the sunspot number (surface density) and frequency splittings should be plotted on the same graph. This approach contrasts with my earlier calculation<sup>2,3</sup> which explicitly predicts the splittings from an asphericity in the sound speed. These model predictions have been confirmed by observation<sup>4</sup>.

In his report<sup>1</sup>, Gough criticizes the limb temperature observations and inferences because they do not account for the variability of the mean solar irradiance measured by ACRIM. In fact the limb data nicely explain<sup>5</sup> the observed cycle variation of the solar constant. Furthermore, the formalism and data directly provide information on the depth dependence of the asphericity. For example, I have used the helioseismic observations to show that the asphericity is best described by a perturbation in the outer superadiabatic layer of the convection zone<sup>6</sup>. Thus, unlike Gough, I find it hard to see how the helioseismic data can be interpreted to explain a measureable solar-cycle variation in the neutrino flux from the Sun's core.

In any case, Gough's 'prediction' may soon be tested. Splitting data from 1988 should show large changes (and significant centroid frequency shifts) from 1987. In contrast with Gough<sup>1</sup> I expect the  $b_1$  ( $\alpha_1$  in ref. 2) splitting coefficient to be even

Time dependence of the helioseismic splitting measurements<sup>3,4</sup>. The most recent photometric observations are from limb photometry obtained in 1988. In contrast with Gough<sup>2</sup>, I expect the  $b_4$  coefficient to decrease in 1988.

smaller than in 1987 (see figure). Note that this is not a correlative inference, but a test of a simple model consistent with observed solar irradiance variations.

JEFF KUHN

Department of Physics and Astronomy,  
Michigan State University,  
East Lansing, Michigan 48827, USA

GOUGH REPLIES — That the even splitting coefficients of solar 5-minute oscillations should arise predominantly from a latitudinal variation in the propagation speed  $c$  of acoustic waves rather than a geometrical distortion of level surfaces is a natural supposition. The frequency splitting  $\delta\nu/\nu$  between sectoral and zonal modes was  $\sim 2 \times 10^{-4}$  in 1982 near the solar maximum<sup>7</sup>, whereas the oblateness at that time was probably no greater than  $2 \times 10^{-5}$  (ref. 8). Moreover the frequency splitting induced by the oblateness is of opposite sign to that observed.

What is the nature of the variation in  $c$ ? The most natural thought is that it is a sound-speed variation, associated with a variation in temperature. Simple models of the solar envelope in which thermal asphericity is induced by magnetic inhibition of convection in the equatorial regions, yet which maintain radial hydrostatic balance, reproduce the splitting data<sup>9</sup>. But they require a photospheric temperature variation that is a hundred times greater than recent observations indicate<sup>6</sup>. What is remarkable, however, is Kuhn's finding<sup>3,4</sup> that if the observed latitudinal variation in relative temperature<sup>6</sup> away from the poles is assumed to extend essentially unmodified through the superadiabatic convective boundary layer, then the splitting data are reproduced.

It was the original failure of plausible hydrostatic-envelope models to explain the splitting data that induced an investigation of magnetic effects, particularly as the asphericity was similar to the sunspot

distribution. A non-uniformly distributed fibril magnetic field of magnitude similar to that observed reproduces the required frequency splitting<sup>9</sup>. It was that result that led me previously to assume a correspondence between magnetic activity, measured by sunspot density, and  $\delta c/c$ .

From an extrapolation of the sunspot data from 1 January 1988 I thus predicted the results of measurements being carried out in Antarctica by a team from the US National Solar Observatory. Recently, R. K. Ulrich kindly provided me with Mt Wilson sunspot data up to 25 November 1988. Using the scaling from my letter<sup>1</sup> these data provide a revision of the prediction to  $\alpha_1 \approx 170$  nHz,  $\alpha_2 \approx -110$  nHz; thus in contrast with my previous extrapolated result  $\alpha_1$  seems still to be declining, in agreement with Kuhn's expectations.

The new discussion of limb brightness measurements<sup>6</sup> was not available when I wrote my first report<sup>1</sup>. The impressive correspondence with the ACRIM data lends considerable credence to the interpretation in terms of effective-temperature variations, and thus demands a consistent theoretical investigation of its implications concerning the dynamical balance of the convection zone and the splitting of oscillation frequencies.

## GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously.

*Nature* is an international journal covering all the sciences. Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields. Please write clearly and simply, avoiding unnecessary technical terminology. *Nature's* staff will edit manuscripts to those ends if necessary. Contributors should check their proofs carefully.

Because of the competition for space, many of the papers submitted for publication cannot be accepted. For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility. Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words.

### CATEGORIES OF PAPER

**Review Articles** survey recent developments in a field. Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator. Length is negotiable in advance but must not exceed six pages of *Nature*.

**Articles** are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding. They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*.

Articles should be accompanied by a heading of 50 - 80 words written to advertise their contents in general terms, to which editors will pay particular attention. A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements. The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications.

Articles may contain a few subheadings of two or three words. The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows. There should be fewer than 50 references.

**Letters to *Nature*** are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field. Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature*. The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study. Letters should not have subheadings or more than 30 references.

**Commentary** articles deal with issues in, or arising from, research that are also of interest to readers outside research. Some are commissioned, most are unsolicited. They are normally between one and four pages of *Nature* in length.

**News and Views** articles are intended to inform non-specialist readers about a recently published advance. Suggestions should be made to the News and Views Editor. Illustrations are welcome. Proposals for meeting reports should be agreed in advance.

**Scientific Correspondence** is for the discussion of scientific matters, including contributions published in *Nature*. Priority is given to contributions of less than 500 words and five references. Figures are welcome.

**Submission.** All manuscripts may be submitted to either London or Washington. They should not be addressed to editors by name. Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value \$5' to prevent the imposition of import duty and value-added tax (VAT).

### GENERAL

All contributions submitted for publication in *Nature* should conform with these rules.

**Manuscripts** should be typed, double-spaced, with a good-quality printer, on one side of the paper only. Four copies are required, each accompanied by lettered artwork. Four copies of half-tones should be included. Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered. Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such. Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers.

**Titles** should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters. Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes.

**Artwork** should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number. Original artwork should be unlettered. Ideally, no figure should be larger than 28 by 22 cm. Figures with several parts are permitted only if the parts are closely related, either experimentally or logically. Suggestions for cover illustrations, with captions, are welcome. Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published.

**Colour Artwork.** A charge of £500 a page is made for 4-colour figures. Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained.

**Figure legends** must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible. The figure should be described first, then, briefly, the method. Reference to a method described elsewhere is preferable to a full description. Methods should not be described in detail in the text.

**References** should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends. Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited. All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate). Text should not be included in the reference list. References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 - 65). The first and last page numbers should be cited. Reference to books should clearly indicate the publisher and the date and place of publication.

**Abbreviations, symbols, units and Greek letters** should be identified the first time they are used. Acronyms should be avoided as much as possible and, when used, defined. Editors will shorten words if necessary. In case of doubt, SI units should be used.

**Footnotes** should not be used except for changed addresses or to identify the corresponding author if different from the first-named.

**Acknowledgements** should be brief. Grant numbers and contribution numbers are not allowed.

## Biotechnology Guide U.S.A. Companies, Data and Analysis

Mark D. Dibner, P.h.D., Director  
Biotechnology Information Center,  
North Carolina Biotechnology Center

**B** iotechnology Guide U.S.A. is a desktop reference that provides you with specific and detailed information on U.S. biotechnology companies. It focuses on the 360 key firms working directly with the new technologies, and gives details of each company and an analysis of the industry as a whole.

The Guide features listings and rankings, which analyze companies by: financing and equity • revenues • R&D budgets and relative importance • personnel • areas of interest • partnerships • patents • subsidiaries • founding and founders • state.

In addition to the analysis of the 360 core companies, the Guide describes the involvement of large corporations in the biotechnology industry, and offers information on the work of the state biotechnology centers.

# Laboratory Science from VCH

## Laboratory Robotics

A Guide to Planning, Programming and Applications

by W. J. Hurst and J. W. Mortimer

1987. XII, 130 pages with 51 figures and 5 tables.  
Hardcover. £ 24.95.  
ISBN 3-527-26675-5

This guide introduces the reader to the concepts, the language, and the reasoning behind the purchase of a lab robot. It tells the practicing scientist or lab manager whether a lab robot may relieve some of the work load. Computers permit control of multiple tasks, thereby permitting serialization of automated procedures. Serialized automation usually leads to higher throughput, greater human productivity, and more uniform results in comparison to manual batch processing. The applications chapter contains 76 useful references to areas such as GPC, BOD analysis, DSC systems, GC, TLC, tensile testing, etc. A chapter on future prospects provides stimulating ideas for further development.

## parat Pocket Dictionary of Laboratory Equipment

English/German

## parat Taschenwörterbuch Laborausrüstung

Deutsch/Englisch

by H.-D. Junge

1987. VII, 201 pages. Softcover. £ 14.95.  
ISBN 3-527-26591-0. ISSN 0930-6862

This pocket dictionary contains the 2500 most common terms for scientific and technical equipment in chemical laboratories. It is a useful tool for those who are used to communicating in German and English, but have to learn the special terminology in this field.

Sterling prices subject to change without notice.

## Practical Experimental Designs and Optimization Methods for Chemists

edited by C. K. Bayne and I. B. Rubin

1986. VIII, 205 pages with 40 figures and 55 tables.  
Hardcover. £ 40.45.  
ISBN 3-527-26195-8

Most experiments in chemistry are conducted for procuring data from which inferences can be made. Statistical methods are used to analyze and evaluate the data obtained. However, it is a common and major error to consider statistics as a tool to be applied only after experiments have been completed. This book presents the view that a major part of planning for an experiment should be consideration of statistical analysis *before* data are gathered in order to make data analysis as efficient and informative as possible. It acquaints its readers with the most efficient ways to achieve this goal. In addition, optimization experiments and response surface methods are discussed and substantiated by a bibliography that guides the reader to current applications in sixteen major fields of chemistry.

## Laboratory Robotics and Automation

A new Journal

1989. Volume 1. Published bimonthly.  
Ca 400 pages. Annual subscription rate  
£ 110.00 plus postage and handling charges.  
ISSN 0895-7533

*Laboratory Robotics and Automation* seeks to serve the interests of the wide variety of individuals involved in laboratory robotics and automation. It covers all aspects of laboratory robotics and automated systems, in particular the applications of commercially available robots, robot peripherals, and laboratory modifications of laboratory-manufactured robots. Applications might involve analytical, synthetic, and environmental chemistry. Other automated systems that are currently available but not classified as true robots or that are involved in sample preparation or the final determinant steps will also be discussed.

# A way with words

Stephen Jay Gould

**The Oxford English Dictionary, 2nd edn.** Prepared by J.A. Simpson and E.S.C. Weiner. Clarendon: 1989. Twenty volumes, £1,500, \$2,500.

THE Brothers Grimm, after a lifetime of service collecting folk tales and developing some basic principles of linguistic evolution, began their greatest project in 1838 — a German dictionary that would illustrate the history of all words found in three centuries of literature, from Luther to Goethe. As the architects of mediaeval cathedrals understood so well, some projects are too big to complete in a lifetime, and satisfaction must reside in a worthy start and a workable plan. Wilhelm, who died in 1859, only reached the letter D, while Jacob, who lived four years longer, got all the way to F. Their great work was finished in our own century.

When James A. H. Murray became the first editor of *The Oxford English Dictionary* in 1879, he faced an even more daunting task — for his project would document all English words in all meanings, active and extinct, from 1150 up to the moment, and including actual quotations for all nuances of use. (The starting point was arbitrary, but sensible as a criterion for the inception of English, allowing about a century after the conquest of 1066 for the Romance language of the victorious Normans to fuse sufficiently with the indigenous Germanic of the vanquished Anglo-Saxons.) Murray anticipated a labour of ten years, and a product of four volumes and 6,400 pages. In 1884, with half his time elapsed, Murray published the first volume, reaching halfway through the first letter to 'ant'. But, as Aesop's grasshopper discovered, industry is an ant's middle name. Murray and his worldwide network, ranging from full-time editors to volunteers from Madras to California, persisted. The task was finished in 1928, long after Murray's death.

A project such as the *OED* cannot end so long as the genealogical skein of English-speaking people persists — for language is the hallmark of humanity, and linguistic change is the primary record of history. Any stated completion could only be an admission of failure. At most, the guardians of this greatest monument in the history of English scholarship may choose, now and again, to mark a way-

station in their eternal updating by issuing a hard-copy version of their dynamic storehouse. (Such overt summations may become less and less necessary as computer technology permits continuous change in electronic versions, with immediate access to all revisions and additions as they occur; though a few die-hards who love the heft, feel and smell of a real volume may — God preserve them forever — keep the art of bookmaking alive.) This second edition, in 20 volumes of 21,728 pages, defining about half a million words with illustrations from about 2.4

million quotations, is both a progress report and one of the greatest causes for celebration in the history of publishing.

The *OED* is timeless in the ethical sense of possessing ultimate and permanent value *in se*. But it is also the child of its time in form and purpose. It began as a project of the Philological Society in 1857 (an effort that delivered nearly 20 years of preliminary work to Murray's later editorship — and he still took five years to reach ant!). Two years later, in 1859, the Society published guidelines for the great work, including two fundamental principles: that "it should contain every word occurring in the literature of the language"; and that "in the treatment of individual words the historical principle will be uniformly adopted". This crucial decision, the foundation of the *OED* ever since, reflects the most enduring and innovative theme of nineteenth-century scholarship in general — the use of historical connection and development as the chief principle of organization and explanation. Geology had burst the bonds of time and provided an ample stage; biology had discovered the genealogical basis of all natural order; anthropology and linguistics were reconceived as historical sciences. It is no accident that these guidelines for the *OED* were published in the same year as Darwin's *Origin of Species*.

In the *OED*, all words are treated as historical entities with origins in etymologies and histories of changing usage. The earliest meanings are presented first, whatever their current status, followed by later developments in genealogical sequence. Since words evolve in the manner of organisms, the editors faced the same problem confronting darwinian taxonomists who had to translate the actual geometry of evolutionary branching into the linear format of a book. They adopted the biologist's convention of listing primary meanings ('species') in linear order (by arabic numerals in the *OED*), but gathering them by groups into higher taxa ('genera'), each representing a separate branch (roman numerals in the *OED*).

This format frees the *OED* from a dictionary's conventional role as the arbiter of 'correct' usage. Standard modern definitions have no pride of place or special designation; they take their proper order in the historical flow. But this format also makes the *OED* the greatest reference book ever written — for it turns each word into a story, and its totality becomes our history, if not our very definition as human. In a world of contingency, no essence exists beyond the labyrinthine and

**ant** (ænt). Forms: 1 (*W. Sax.*) æmete, -ette, -ytte, 3-4 amete (amote), amte, 4-6 ampte, 5-6 ante, 5-7 annt, 6- ant. Also 1 (*Anglian*) \*ēmete, 3-4 emete (-atte), 4-6 emote, 6 emmette, -otte (-ont), amyte, emet, 6-7 emmot(t, 6- emmet. *Pl. ants* (1 æmetan, 2-4 ameten, 4 amptes). [OE. æmete, ēmete, cogn. w. OHG. āmeiza, WGer. \*āmaitjō, f. ā- (see *Æ-* pref.) off, away + maitan, ON. meita, OHG. meizan 'to cut,' as if 'the cutter or biter off.' (Graff.) The OE. became in 12-13th c. āmete or ēmete in different dialects; āmete has by suppression of medial vowel and bringing together of two consonants become amte (ampte), ante (cf. account for accompte), ant; ēmete, retaining the medial vowel, is now EMMET, q.v. *Ant* is the leading literary form.]

1. a. A small social insect of the Hymenopterous order, celebrated for its industry; an emmet, a pismire. There are several genera and many species, exhibiting in their various habits and economy some of the most remarkable phenomena of the insect world. (For other quotations see EMMET.)

b. In colloq. phr. to have ants in one's pants (orig. U.S.), to fidget constantly, esp. because of extreme agitation, excitement, nervousness, etc.; to be impatient or restless. Cf. ANTSY a.

[1939 KAUFMAN & HART *Man who came to Dinner* 1. ii. 62 'I'm in love.' 'I'll pull you out of this Miss Stardust. I'll get the ants out of those moonlit pants.'] 1940 'C.

unpredictable paths of historical development. The *OED* is the ultimate companion for those lonely years on a desert island in our standard *Gedanken* experiment. We consult it for a definition, and invariably emerge with an adventure. Half a million stories to last for as many thousand-and-one nights as any person can endure. (I'm not sure that I would trade my *OED* even for Scheherazade herself.)

Start anywhere. 'Chemistry' began with two extinct meanings as alchemy and paracelsian versus galenic medicine. Its modern definition dates from the seventeenth century, but the vernacular meaning of "instinctual and unanalysable attraction or affinity between people" is even older — dating from a comment of Queen Elizabeth (the first one) in 1600, and not to the beaches of modern California. 'Physics', thanks to Aristotle, is an even older word, but it encompassed all nature (even including God and spirits according to Locke) until eighteenth-century usage began to split the organic and inorganic worlds. 'Biology' is a relative newcomer, dating only from the German Treveranus and the Frenchman Lamarck in 1802 (with the first use in English in 1813).

'Science' (from the Latin *scire*, to know) goes back to the beginning, but as a general word for systematized knowledge of any sort (Chaucer wrote about "a science of good works"). The modern usage follows a series of branching and progressive confinement. Science began to separate from art in the eighteenth century, but restriction to knowledge about the physical and natural world only occurred in the mid-nineteenth century. Keeping abreast of the latest developments, the final definition presents 'science park', with an American source of 1972 for first usage.

Related words teach us more. 'Scientism' was used in a purely descriptive sense as early as 1877, but the modern derogatory meaning dates from G.B. Shaw in 1921 — in *Back to Methuselah*, and with a capital S ("The iconography and hagiology of Scientism are as copious as they are mostly squalid"). The concept of 'scientist' may date from the Domesday Book, but the word only goes back to 1834. The *Quarterly Review* then noted "the want of any name by which we can designate the students of the knowledge of the material world collectively". "This difficulty was felt very oppressively" at a recent meeting

of the British Association for the Advancement of Science. The nameless attendees considered philosopher as "too wide and lofty" and "savans" (*sic*) as "rather assuming". "Some ingenious gentleman" then suggested "scientist" by analogy with artist, claiming "no scruple" for the odd termination of *ist* by noting

James A.H. Murray, word collector extraordinary.

its acceptance in "economist" and "atheist". "But this was not generally palatable", the *Quarterly* reports, and scientist might have died aborning, if William Whewell had not taken up the cause in 1840. And a good thing too — or we might have been saddled with "scientman", proposed once in 1636, but quickly exterminated.

The three-page entry on 'nature' is a fascinating treatise on English thought about essential qualities (the original definition of properties held by birth, or natively). Category I speaks of the "essential qualities of things"; II of vital or physical powers in humans, including two extinct meanings ("semen or menses" in a lineage extending from Chaucer to James Joyce, and "the female pudendum, especially that of a mare" extending from Caxton through to the eighteenth century); III of the power or impulse directing or controlling human action (as opposed to grace); IV (now getting close to modern scientific usage) as regulative powers that control the physical world, or

even (but not until the seventeenth century), "the material world with its objects and phenomena". This last (and the basis, I assume, for the name of this journal), is category IV, definition 13 in the *OED*. Nature, by the way, has been personified as female ever since Chaucer.

As a vast collective project the *OED* is far from perfect, and inevitably so. But our complaints can only represent lovers' quarrels. I caught some vestiges of Victorian origins — references to the tools and habits of "African savages", for example. I found serious errors and omissions in the few words that I have studied intensely ('evolution' is badly served because the compiler did not grasp the full extent of pre-darwinian biological usage for the embryological theory of preformation). Some extinct words receive too much play (the complex terminological apparatus for Weismann's incorrect theory of heredity), while others now in vogue have not come to the *OED*'s attention (the far less complex terminology for evolutionary change in the timing of development).

This work needs no medals, no citations, no words of praise. It stands by and for itself, as a gift to all intellectuals. The truly great, in supreme and justified confidence, merely present themselves — *ecce homo, ecce res*. Christopher Wren has no gravestone, only a simple plaque on the floor of his greatest building, St Paul's Cathedral, engraved with the words: *si monumentum requiris, circumspice* (if you are searching for a monument, look around). For the *OED*, we need only say: *si monumentum requiris, inspicere* — look within. □

## Big business

Marco Festa-Bianchet

**Megaherbivores: The Influence of Very Large Body Size on Ecology.** By R.N. Owen-Smith. Cambridge University Press: 1988. Pp. 369. £40, \$64.50.

MEGAHERBIVORES are terrestrial herbivores that weigh over 1,000 kg: elephants, rhinos, hippos and giraffes. Biologically they are unique in several respects. For example, as adults they are almost completely beyond the reach of non-human predators. They also efficiently use low-quality forage; and because they need a lot of it, they have a great effect on ecosystems, and on the kinds and numbers of plants and animals that share their environment.

In his book devoted to these huge creatures, Owen-Smith first considers

their ecology, physiology and behaviour. In most cases, he presents a test of whether they are just especially large in size or are different from what may be predicted by extrapolating allometric relationships of smaller herbivores. He discusses the limitations inherent in the quality of the available data and in the statistics used to analyse them. Megaherbivores are difficult to study. Their longevity and slow reproductive rate, coupled with human exploitation and habitat destruction, cast uncertainty over the causes of particular ecological processes; for example, habitat fragmentation may prevent animals from dispersing and lead to severe habitat degradation. Perhaps in the past megaherbivores avoided this problem by moving to new areas. Exploitation by human beings probably affected population dynamics and habitat characteristics, so that it is sometimes unclear which changes in vegetation structure are a normal feature

of the community ecology of megaherbivores, and which result from the cessation of exploitation and sudden population increases in habitats whose structure changed while numbers were kept low.

The middle chapters of the book vary in scope. In some, for example those on nutrition, feeding ecology, reproduction and ecosystem processes, Owen-Smith can consider all megaherbivores as a group, and tests well-defined hypotheses. In others, such as those on behaviour and demography, differences between the species force less interesting species-by-species summaries of data. All chapters provide good literature reviews.

Most of the book is a prelude to two arguments presented at the end, where Owen-Smith puts forward explanations of the Pleistocene extinctions and discusses the conservation of surviving species.

Megaherbivores, once distributed over all continents, are now restricted to eight species in Africa and tropical Asia. Only hippos and giraffes appear to be safe over most of their range. Yet local problems of overpopulation show that "megaherbivores are embarrassingly successful when protected from human depredation".

The explanation for Pleistocene extinctions has human overexploitation as the main driving force, but takes into account climatic shifts and changes in habitat characteristics. Owen-Smith suggests that it was hunting that caused the demise of megaherbivores, especially in North America and Europe, and that changes in habitat (leading to extinction of some smaller species) were an effect and not a cause of their disappearance.

The chapter on conservation is excellent. Owen-Smith believes management is necessary for conservation, because artificial habitat fragmentation prevents dispersal of animals. He also recognizes that 'overgrazing' and 'overpopulation' are not biological realities, but reflect management choices. Protected from poaching, megaherbivores could recover to levels where light exploitation would be both feasible and desirable — but "without effective controls of illicit markets, populations of these great beasts will be driven inexorably towards extinction". □

## On course for a better life?

F.E.G. Cox

**The Biology of Parasitism.** Edited by Paul T. Englund and Alan Sher. Alan R. Liss: 1989. Pp. 544. Hbk \$90, pbk \$45. Distributed in Britain by Wiley, hbk £68.85, pbk £35.50.

EACH summer since 1980, a small group of young scientists has gathered at Woods Hole to attend a course on advances in the molecular biology and immunology of parasites. The course is given by acknowledged experts from all over the world, and serves as a barometer of the state of the subject. In this volume, a number of the lecturers have attempted to convey its flavour and spirit to a wider audience. In all, 41 scientists have contributed 28 chapters, grouped into biological, immunological and molecular biological, biochemical and genetic aspects of parasitism, to produce a book that attempts to reflect the present state of our knowledge and to be an essential aid in undergraduate and postgraduate teaching.

The stated aim is to emphasize concepts rather than review research data, but sadly some of the authors have ignored this principle and the volume is thus very varied in content. Things get off to an excellent start with accounts of the global impact of parasitic diseases by Ken Warren, and of parasitic zoonoses by George Nelson, which set the scene. There are also specialized chapters on human schistosomiasis, amoebiasis, American leishmaniasis and trypanosomiasis and, towards the end, on toxoplasmosis, that are stimulating and make

provocative points.

The first SDS-PAGE gel appears on page 97, closely followed by the inevitable contributions on the surface antigens of *Plasmodium falciparum*, thick with facts and thin on concepts. The surface antigens of trypanosomes also receive considerable attention in three chapters; in one of them, John Donelson manages to concentrate on essentials and to ask interesting questions, as does Alan Sher in his contribution on vaccination. Fresh ground is explored by C.C. Wang, who considers new targets for chemotherapy, but his is the only contribution on this important area. Most of the remaining chapters are largely mini-reviews of topics covered in depth elsewhere.

Overall, this collection of articles represents a fair overview of present-day parasitological research and pin-points the unevenness of the subject's coverage. The important matter is the extent to which knowledge gleaned in the main laboratories of the world can be applied to the immense problems outlined by Ken Warren, and it is disturbing that most of the questions asked are of an academic rather than a practical sort. Equally disturbing is that scrutiny of the faces in the photographs of those who attended the last eight courses reveals that only three are black. One is tempted to ask whether parasites are important because they are the playthings of immunologists and molecular biologists or because they are daily life-threatening components of the environment for millions of people. Whatever the answer, the editors have produced a book that is useful, readable and well worth having. □

# Measuring up the planet

Barry Parsons

**Geophysical Geodesy: The Slow Deformations of the Earth.** By Kurt Lambeck. Clarendon: 1988. Pp.718. Hbk £75, \$95; pbk £30.

GEODESY, which can claim to be the oldest of the geophysical sciences, maintains a somewhat different relationship to geophysics than the other geophysical sciences. The choice of *Geophysical Geodesy* as a title to emphasize that this book is about the geophysical applications of geodesy points to the usually dominant role of applied aspects of the subject. In contrast the title of a book on seismology would probably only be qualified if it were about exploration or engineering seismology.

This difference can be explained in part by the long timescales involved in the development of many geodetic techniques. Consider the example of very-long-baseline interferometry (VLBI), which is the method of determining the distance between two points on the Earth's surface by using radio telescopes at the two sites to measure the small differences in arrival time of signals from distant radio sources. It has taken 20 years of painstaking development for VLBI to get to the stage where it is possible to measure directly the relative motion between the tectonic plates. Although most geophysicists appreciate the potential of many geodetic measurements, their interest is only really aroused when it becomes clear that worthwhile information about the Earth will be forthcoming.

Fortunately for those interested in the geophysical applications of geodesy, in recent years several geodetic techniques have emerged that have either already demonstrated their value in studying the Earth or seem about to do so. Satellite altimeter measurements of the shape of the ocean surface have replaced direct measurements of gravity as the primary source of information about the gravity field over the oceans. These observations provide one of the few ways of looking at the effects of mantle convection beneath the oceanic lithosphere. In the next few years the Global Positioning System will become fully operational, and this method of measuring baseline lengths, which is similar to VLBI except that satellite radio sources rather than extraterrestrial ones are used, has the potential to determine exactly how crustal deformation in the tectonically active regions of continents takes place. The nature of the core-mantle boundary is the subject of much debate, and VLBI observations of the nutations of

the Earth's rotation axis allow estimates to be made of the departure of the ellipticity of the core-mantle boundary from the ellipticity expected due to the Earth's rotation alone.

Against this background, Kurt Lambeck has set himself the task of writing an account of the subject that encompasses not only the geodetic techniques but the geophysical applications as well. The breadth of material he covers is impressive, and the book will provide an excellent overview of the field for both students and research workers. Such a comprehensive treatment within a single volume has its drawbacks, however. The author has to assume that the intended audience of graduate students will already have been exposed to the basic ideas of both geodesy and geophysics, an assumption that will only be true for the more advanced

student. In addition, by introducing many results without the concomitant theoretical development, one loses a sense of the physics that lies behind the equations.

The subtitle, *The Slow Deformations of the Earth*, reflects the author's interests and the contents of the book are clearly weighted towards solid-Earth geophysics. Physical oceanography, which will be the principal beneficiary of the two satellite altimeter missions due over the next five years, appears in a subordinate role. Yet, with the broad range of geophysical applications that are included, and its appearance just as new observations are about to flood in, this book is bound to attract a wide audience. □

Barry Parsons is Reader in Geodesy in the Department of Earth Sciences, University of Oxford, Parks Road, Oxford OX1 3PR, UK.

## Today's data

Gunnar von Heijne

**Computational Molecular Biology: Sources and Methods for Sequence Analysis.** Edited by Arthur M. Lesk. Oxford University Press: 1988. Pp.254. £25, \$49.95.

FIVE years ago, in the typical molecular biology laboratory, there would be at least one computer whiz kid: a graduate student who stole time away from the bench to break into the central campus computer and entertain himself with adventure games. This student was often quickly assigned the more serious job of taking care of the sequence-analysis needs of the lab, installing the newly purchased software that no one else had found the time to get running. Thus everybody was happy: the student was promoted to the status of computer expert, and the 'real' scientists didn't have to soil their hands at the PC keyboard.

Times have changed. Even the staunchest 'wet' experimentalist has had to adapt to the fact that these days one simply cannot do molecular biology without occasional recourse to the help of a computer. This, of course, is mainly a result of the extraordinary growth of DNA sequence data over the past ten years: more than 20 million bases worth of sequence is now stored in the main data banks such as GenBank or the European Molecular Biology Laboratory's data library, and only computers can deal with such massive amounts of information.

The world of 'machine molecular biology' is not immediately accessible to the average biologist, however, and good introductory texts are badly needed. The so-called CODATA Task Group on Coordination of Protein Sequence Data

Banks has now put out a volume called *Computational Molecular Biology*, edited by Arthur Lesk, to meet the demand.

The book is organized around four questions — What data are available? How can one gain access to them and to the necessary programs? What calculations can be done? And how can the results of the calculations be intelligently and cautiously interpreted? The first and second questions are treated at length; the third and fourth are less fully explored. We thus learn a lot about a number of DNA- and protein-sequence data banks around the globe, and we are introduced to the hardware and software of sequence analysis as well as to some aspects of computer networking. But we are told less about the actual methods and algorithms that allow the computer to produce the output we want.

Lesk apparently sensed this bias at an early stage, and has written a number of the less 'computerish' chapters himself, chapters for people who care more about how to find probable coding regions, or predict the structure of a protein, than about the details of how a GenBank entry is organized. Lesk has also come up with a couple of remarks that I will cherish for a long time to come. Thus, in summing up secondary structure prediction for proteins, he delivers the following: "Running a secondary structure prediction on a newly-determined sequence just because everyone else does so, is to be deplored, and the fact that the results of such predictions are generally ignored is insufficient justification for doing and publishing them". This is the sort of text that should be printed on every sequence-analysis software diskette as a 'Warning from the Surgeon General'. □

# The search for the causes of breast and colon cancer

Walter Willett

Epidemiological studies of breast and colon cancers implicate diet as a causative factor but the evidence is stronger for colon cancer, the occurrence of which may be reduced by diets with less animal fat and more fruit and vegetables.

AMONG non-smokers, cancers of the breast and colon are the most important malignancies in Western societies. By the age of 75 years, over eight per cent of women in the United States will develop breast cancer and about three per cent of both sexes will be diagnosed as having colon cancer<sup>1</sup>. Another one to two per cent of men and women will develop rectal cancer by the time they are 75; although this is sometimes not distinguished from colon cancer, it will not be considered here because some of its epidemiological features are distinct. Treatment of breast and colon cancer remains disappointing. Hence, considerable interest has focused on determining the causes of these cancers, with the hope that such knowledge will lead to practical means of prevention.

The occurrence of both breast and colon cancer is strongly associated with modern affluence, suggesting that they may share important aetiological factors. Indirect evidence, largely based on differences in cancer rates between countries and changes in rates among migrants, has implicated diet as potentially important, but specific aspects of diet have not yet been definitively identified from epidemiological investigations. Much of the available information is derived from case-control studies in which reports from cancer patients about their past dietary practices are compared with those of persons without cancer. The possibility of biased reporting of former diets in these studies is difficult to eliminate. Prospective cohort studies, in which dietary variables measured among a large number of people are related to subsequent risks of cancer, should provide more dependable data, but these are only beginning to be available because it takes time to accumulate enough cancer cases. The existing limited data suggest that, despite gross similarities in the epidemiology of breast and colon cancer, incidence of the colon cancer is likely to be more responsive to dietary change and thus be easier to prevent.

## Roles of environment and genetics

Evidence is strong for a substantial genetic contribution to the risk of breast and colon cancers. Having a first-degree relative with breast cancer increases risk by about 1.5–3 fold<sup>2,3</sup>. Although this familial association could conceivably be due to a shared environment, the much higher risks (approximately tenfold) associated with some familial patterns, such as having a mother or sister with bilateral breast cancer at a young age, makes it more likely that the familial associations are genetically based. Even one case of colon cancer in a first-degree relative increases the risk for other family members by approximately threefold<sup>4,5</sup>.

Nevertheless, genetic factors are not the only explanation. Rates of breast and colon cancer vary strikingly between countries, by five to tenfold<sup>6</sup>, and migrants moving from low- to high-risk countries adopt the rates of the new country<sup>7,8</sup>. Furthermore, there have been large increases in rates in some countries during this century<sup>9,10</sup>. Thus, both breast and colon cancer almost certainly involve a strong interaction of genetics and environment. Without the necessary environment, few will develop these diseases; but in a suitable environment, those with a genetic predisposition will be at high risk. Aetiological

studies of breast and colon cancer will become far more powerful when specific genetic markers for predisposition become available.

Differences in rates between countries have been used to estimate that 90% of colon and 80% of breast cancers in the United States of America can be attributed to non-genetic factors<sup>11</sup>. The challenge is to identify the specific environmental factors. Although there is a plethora of hypotheses, well established risk factors are few and do not account for the major international differences or lead directly to practical preventive measures. Diet is a prime candidate: Doll and Peto<sup>11</sup> have suggested that as much as 50% of breast and 90% of colon cancer in the United States might be prevented by changes in diet. Before examining specific dietary hypotheses, the better established risk factors will be briefly discussed.

## Risk factors for breast cancer

As early as 1700, Ramazzini<sup>12</sup> observed that child-bearing reduces the risk of breast cancer. In an international study, MacMahon *et al.*<sup>13</sup> found that the dominant protective factor was an earlier age at first birth, rather than the number of children: a first birth after the age of 35 years increased the risk about threefold compared with a first birth before the age of 20. Other data suggest that having a larger number of children also independently reduces the risk<sup>14,15</sup>. The protective effect of early first full-term pregnancy may be due to a permanent differentiation of mammary stem cells, resulting in a reduced lifetime risk of breast cancer<sup>16,17</sup>.

Many studies show an association between early age at menarche and increased risk of breast cancer; typically early menarche confers about a 1.5–2 fold increase in risk compared with late menarche<sup>14,18,19</sup>. Early menopause provides protection<sup>14,20</sup>; removal of both ovaries before the age of 35 reduces the risk of disease by about 0.6 compared with natural menopause. These associations with reproductive factors provide support for a hormonal role in the aetiology of the disease<sup>21,22</sup>.

The relationship between sex hormone levels in blood or urine and risk of breast cancer have been examined in many studies but clear and consistent findings have not emerged. All these studies have been small, however, and most have been conducted among patients who already have cancer, who may have had altered hormone levels because of the disease. Key and Pike<sup>23</sup> concluded in a recent review that the data overall suggest a promoting effect of oestrogens and possibly also of progestagens.

The possible role of sex hormones in the development of breast cancer has raised concerns that oral contraceptives and post-menopausal replacement hormones might increase the incidence of this disease. Overall, little relationship has been seen between oral contraceptive use and breast cancer<sup>24</sup>, but longer-term use before a first full-term pregnancy may elevate risk<sup>24,25</sup>; more data are needed to resolve this important issue. In most studies, oestrogen-replacement therapy after menopause has not been associated with the incidence of breast cancer<sup>26</sup>, but use of hormones for several decades may cause a modest

increase<sup>27</sup>. Most investigations have concentrated on past users and the possibility that current use may promote tumour growth has generally not been addressed.

Ionizing radiation, including that of X-rays, is a well-documented cause of breast cancer, especially for exposure during adolescence<sup>28,29</sup>, but this cannot account for a large proportion of the disease because not many women receive a significant exposure. Benign lesions are probably best considered as pre-malignant responses to primary aetiological factors: the subsequent risk of breast cancer is strongly related to the degree of proliferative change and atypia found in biopsies of such lesions<sup>30</sup>.

### Risk factors for colon cancer

Few specific risk factors for colon cancer have been established. Inflammatory bowel diseases, such as ulcerative colitis and Crohn's disease, greatly increase the risk<sup>31</sup> but because of their rarity, these account for a very small proportion of cases. The rare familial polyposis syndromes are associated with high risk<sup>31</sup>, but also contribute only slightly to the overall incidence of colon cancer.

The presence of adenomatous colon polyps, which can be considered as precursor lesions<sup>32</sup>, is associated with an elevated risk of colon cancer. Because the polyps can be examined directly by endoscopy, they provide a way of studying the progression to colon cancer that does not exist for breast cancer.

### Diet and cancers of the breast and colon

**Dietary fat and breast cancer.** For the last decade, the dominant aetiological hypothesis for breast cancer has been that high fat intake, and animal fat in particular, is the primary cause of the large differences in rates between countries<sup>33</sup>. This notion is based largely on two lines of evidence: striking international correlations (approximately 0.80) between *per capita* consumption of fat and breast cancer rates<sup>8</sup>; and animal experiments in which diets high in fat increase the occurrence of mammary tumours. Subsequent evidence has not, overall, supported this hypothesis.

It is tempting to draw causal inferences from the international correlations, but these studies provide only weak evidence because the actual causes might involve many other factors related to economic development. Factors such as physical activity, reproductive variables, body composition at different times in life and energy balance are particularly difficult to measure and control in correlational analyses. A recent survey of cancer rates in 65 rural counties in China with similar low levels of economic development<sup>34</sup> strongly suggests that the international comparisons are seriously confounded by factors related to industrialization: fat intake ranged from 5–47% of energy but breast cancer rates did not vary with fat intake and were at most about one-tenth of those in the United States.

Case-control studies and prospective cohort studies provide more opportunity to measure and adjust for other factors that may be related to risk of cancer. For breast cancer, no material association with fat intake has been found in case-control studies from New York<sup>35</sup>, Hawaii<sup>36</sup>, Australia<sup>37</sup>, Greece<sup>38</sup> and Japan<sup>39</sup>. Although a study from Canada was originally reported as showing a positive association<sup>40</sup>, it was not statistically significant and examination of the data indicates that the average fat intake reported by cases was virtually identical to that reported by controls. In other case-control studies, only a limited list of foods was included<sup>41–46</sup>; some have construed sporadic associations with foods containing fat as evidence that fat causes breast cancer. These data are difficult to interpret because of the tendency to focus on foods within a study for which associations are seen and because other aspects of the diet, including total energy intake, cannot be controlled for.

The potential for distortion of associations because of differential recall of past diet is inherent in case-control studies but is eliminated in prospective investigations. Only two pros-

pective studies with a comprehensive assessment of diet have been published. In the larger, based on a dietary questionnaire completed by 89,538 registered nurses in the United States in 1980<sup>47</sup>, weak inverse associations with incidence of breast cancer were seen for total, saturated, and polyunsaturated fat. In the other, there was a statistically significant protective effect of total dietary fat but this inverse relationship was weaker and no longer significant after controlling for total energy intake<sup>48</sup>. In prospective studies with limited dietary data, a positive association was seen with meat intake in Japan<sup>49</sup> but not among Seventh-Day Adventists in California<sup>50</sup>. In the latter, breast cancer rates tended to increase, rather than decrease, the longer a Seventh-Day Adventist vegetarian diet, which contains substantially less animal fat than the general diet of North Americans<sup>51</sup>, was consumed.

Findings from case-control and prospective cohort studies, which generally fail to support the dietary fat hypothesis, have been criticized on the basis that diets in the populations studied are not sufficiently heterogeneous and the methods for measuring diet are not accurate enough to detect potential associations<sup>52,53</sup>. But even when the degree of measurement error associated with the dietary questionnaire used in the larger of the two prospective studies is accounted for<sup>47</sup>, the data are compatible with only a very weak positive association with fat intake<sup>54,55</sup>. Viewed another way, if the positive associations suggested by the international data were true, the inverse associations actually seen in the two prospective studies would be statistically extremely unlikely.

The published case-control and cohort studies cannot exclude the possibilities that reducing fat intake to well below 30% of total energy intake, the level now frequently recommended<sup>33,56</sup>, or at an earlier period in life, might influence breast-cancer rates. No appreciable reductions in breast-cancer risk among vegetarian nuns<sup>57</sup> and Seventh-Day Adventists<sup>58</sup> have, however, been observed, which argues against an important influence of animal fat over several decades.

The relationship between fat intake and the occurrence of mammary tumours in animals, which cannot be reviewed in detail here, remains controversial<sup>59,60</sup>. Restricting energy intake dramatically lowers the incidence of mammary tumours. As fat is uniquely dense in energy, a low-fat diet also tends to be low in energy unless the available energy intake is carefully controlled. Thus, rats on a low-fat *ad libitum* diet have lower tumour incidence than those on a high-fat *ad libitum* diet; in one typical study<sup>61</sup>, a reduction of 40% was seen. In the same study, however, when the high-fat diet was restricted to provide 20% less total energy intake, tumour incidence decreased by 90%.

FIG. 1 Correlation between intake of meat per person and the incidence of colon cancer among women in 23 countries<sup>6</sup>. The strong positive association suggests that animal fat or protein may increase the risk of colon cancer. Because the countries with high meat intake and colon cancer rates tend to be affluent Western nations that differ in many ways from the countries with low meat intake and colon cancer rates, these data are far from conclusive.

Albanes<sup>62</sup> has performed a meta-analysis of the experiments on diet and mammary cancer in mice over the past 50 years, in which he finds an extremely strong overall positive association for total energy intake. After adjustment for total energy intake, the fat composition showed a weak inverse relationship to incidence of mammary tumours. In another review of animal experiments, Birt<sup>59</sup> concluded that there is evidence for an effect of dietary fat which is independent of total energy intake.

Is any particular rodent model relevant to human breast cancer? The models usually involve a potent carcinogen or exposure to a mammary tumour virus, extreme contrasts in diet, and observations for relatively short periods before menopause. In a recent study<sup>63</sup> that more closely simulated the human experience, the occurrence of spontaneous mammary adenocarcinomas was investigated among more than 5,000 female rats and mice randomly assigned to either a 10% fat diet or corn-oil supplements that increased fat to 30% of calories. Even though the animals fed corn oil gained more weight than those on low-fat diets, the two-year cumulative incidence among rats was 2.5% on low-fat and 1.5% on high-fat diets. Among mice, the corresponding incidence rates were 1.7% and 1.3%. A case-control study of breast cancer in dogs, which was conducted by interviewing owners about the usual foods consumed by their animals<sup>64</sup>, revealed an extremely wide variation in dietary fat composition but no association with risk of breast cancer. A consensus clearly does not exist at present that the total fat composition of the diet in animals influences the risk of mammary tumours, so laboratory data cannot be used as an argument for or against any relationship in humans.

The plausibility of the fat-and-breast-cancer hypothesis would be greatly enhanced if it could be shown that fat influences a biochemical mediator of breast cancer, but unfortunately no such mediator has been well established. Blood or urinary oestrogen levels are the most promising candidates, but the relationships between diet and hormone levels are unclear at present<sup>65-67</sup>.

**Dietary fat and colon cancer.** In contrast to breast cancer, epidemiological studies provide some, but not conclusive, evidence that animal fat or meat intake is associated with risk of colon cancer. In comparisons between countries, rates of colon cancer are strongly associated with intake of animal fat and meat (Fig. 1). High total fat intake has been associated with increased risk of colon or rectal cancer in case-control studies from Canada<sup>68</sup>, Australia<sup>69</sup>, Utah<sup>70</sup>, England<sup>71</sup>, New York State<sup>72</sup> and eastern Australia<sup>73</sup>, although the last study is suspect as data from controls were not collected concurrently. In similar studies from southern France<sup>74</sup>, Paris<sup>75</sup> and Belgium<sup>76</sup>, however, no association was found. In the French and Belgium studies, intake of vegetable fats was inversely related to risk of colon cancer. The numbers of colon cancers in prospective studies have been relatively small. Among Japanese-Hawaiian men, those with the highest fat intake had a reduced risk of colon cancer<sup>77</sup> and among Chicago men no association was found between fat intake and colon cancer<sup>78</sup>. In preliminary reports, animal fat intake was positively associated with risk of colon or large bowel cancer among the 89,538 women in the Nurses' Health Study<sup>79</sup> and among 35,000 Seventh-Day Adventists<sup>80</sup>.

In case-control studies of diet and colon cancer, there is a notably consistent positive association with total energy intake<sup>68-72</sup>. This is particularly puzzling because higher energy expenditure seems to reduce risk of colon cancer<sup>81,82</sup> and obesity is unrelated, or at most weakly associated, with this disease (see below). The positive association with total energy intake has important implications for interpreting data on specific nutrients, because all tend to be correlated with total energy intake<sup>83</sup>. It is important to adjust statistically for total energy intake in the analysis of these studies to distinguish between the effect of overall food intake and that of dietary composition, especially for nutrients such as dietary fat that are highly correlated with energy intake. Individuals must alter their intake of

specific nutrients primarily by manipulating the composition rather than the total amount of food eaten, unless they are to alter substantially their physical activity or weight. Thus, the intake of nutrients adjusted for total energy intake is most informative for making decisions about changes in diet. The association of dietary saturated fat with colon cancer was independent of total energy intake in one study<sup>84</sup> but not in another<sup>69</sup>; most other case-control studies have not evaluated whether the observed association with overall fat intake is independent of energy intake.

Plausible mechanisms exist for an influence of dietary fat on the incidence of colon cancer; higher fat intake increases excretion of bile acids and the growth of colonic bacteria capable of converting bile acids to carcinogenic substances<sup>85,86</sup>.

### Dietary fibre

Burkitt's hypothesis<sup>87</sup> that dietary fibre (non-digestible complex carbohydrates) reduces the incidence of colon cancer seems to be, at best, an over-simplification. Increased intake of fibre is thought to reduce the transit time for faecal matter in the gut, and to dilute potential carcinogens in the faeces<sup>88</sup>. High intake of fruits and vegetables has been consistently related to lower risk of colon cancer but consumption of cereal products has not. Although countries where there is a lower intake of fibre tend to have higher rates of colon cancer<sup>89</sup>, inverse associations have been seen in some<sup>70,72,73,76</sup> but not all<sup>68,74,69,71,75</sup> case-control studies.

Some of the inconsistency may result from inadequate adjustment for total energy intake, for even the direction of association can depend on whether energy intake is appropriately considered in the data analysis<sup>70</sup>. Evidence that grain products are protective is considerably weaker than it is for fruits and vegetables; in all eight studies in which the sources of fibre were examined separately, grain fibre or cereal intake was either unrelated or positively associated with risk of colon cancer, whereas intake of fibre from fruits and vegetables was protective<sup>69,74,82,90-94</sup>. A protective effect of fruits or vegetables was also found in two additional case-control investigations<sup>95,96</sup>.

Although the evidence that fruits and vegetables are protective is strong, the specific foods related to reduced risk are poorly defined and the responsible factors are unknown. Specific fractions of fibre may be the active agents; other candidates include vitamins, such as C or E, protease inhibitors<sup>97</sup> and indoles<sup>98</sup>. In one analysis, no association was found with  $\beta$ -carotene<sup>99</sup>, whereas an inverse relationship was seen in another<sup>92</sup>.

More limited evidence indicates that some vegetable factor may be protective for breast cancer, which was found to be inversely related to vegetable intake among women in Greece<sup>100</sup> and to total vitamin A intake, largely from vegetable sources, among women in New York State<sup>101</sup>. This possibility requires further examination.

### Alcohol

Rapidly accumulating evidence, summarized elsewhere<sup>102</sup>, indicates that intake of alcoholic beverages is associated with a higher risk of breast cancer (Fig. 2). Positive associations with beer, wine and liquor in various populations indicates that the effect is due to alcohol *per se*<sup>103</sup>. The possibility cannot be entirely excluded that some other characteristic of women who drink alcohol might explain this association, but such a characteristic would have to cause a larger attributable fraction of breast cancers than the known risk factors and also be strongly associated with alcohol use. When risk factors for breast cancer were allowed for, the association with alcohol was not materially altered in any of the published studies. If the association is truly one of cause and effect, possible interactions with other risk factors may be important. In one case-control study<sup>104</sup>, only alcohol consumed before the age of 30 years contributed to increased risk. If confirmed in other studies, this would mean that if a middle-aged woman reduced her alcohol consumption,

it would not alter her risk of breast cancer.

In a recent cohort study there were higher rates of colon cancer among regular drinkers, especially women, than among non-drinkers<sup>105</sup>. Further prospective data are needed that clearly distinguish colon from rectal cancers, for which the data implicating alcohol are somewhat stronger. A weak positive association, reviewed elsewhere<sup>105</sup>, between use of alcoholic beverages and risk of colon cancer has been observed sporadically in case-control studies.

### Other specific dietary factors

Many other dietary factors have been postulated as either protective or causative for breast and colon cancer. Putative protective factors include selenium<sup>106</sup>, vitamins C<sup>107</sup> and E<sup>108</sup>, preformed vitamin A and its precursor,  $\beta$ -carotene<sup>109</sup>; vitamin D<sup>78</sup>, naturally occurring inhibitors in plants such as the indoles<sup>98</sup>, protease inhibitors<sup>97</sup> and fish oils<sup>110</sup>. Other causative factors suggested include specific fatty acids, such as the *trans*-isomers produced in processing vegetable oils<sup>111</sup>, and mutagenic products formed in the cooking of food<sup>112</sup>. Calcium may reduce risk of colon cancer<sup>113</sup>; reduced colonic epithelial-cell proliferation has been reported in subjects supplemented with calcium carbonate<sup>114</sup> and there is some epidemiological evidence<sup>78,115</sup>. Data are at present too limited either to refute or to confirm any of these hypotheses with confidence.

### Energy balance

In animals, restricting energy intake reduces the occurrence of mammary and colon tumours and other neoplasms<sup>60-62,116,117</sup>; accumulating evidence suggests that reduced energy intake, particularly early in life, may also reduce the incidence of breast cancer in humans. The influence of energy intake on cancer risk in humans is best studied using physical measurements that reflect energy balance at different periods in life. Substantial restriction of energy intake before the age of 20 will stunt height. Among adults, weight standardized for height and measures of change in weight are sensitive indicators of long-term energy balance.

Internationally, the high correlation (0.8) between the average height of adult women in a country and national rates of breast cancer<sup>118</sup> provides some evidence for a protective effect of energy restriction before adulthood. Positive associations have been found between height and risk of breast cancer in several countries that experienced periods of food shortage, such as Greece<sup>119</sup>, the Netherlands<sup>120</sup> and Japan<sup>121</sup>. In the United

States<sup>122</sup> and Scandinavia<sup>123</sup>, height is generally unrelated to breast cancer, compatible with a sufficient supply of energy for most individuals to attain their genetically determined maximum height. In a recent sample of women from the United States,<sup>124</sup> that was enriched in individuals at increased risk of malnutrition, a positive association between height and risk of breast cancer was found<sup>124</sup>.

The relationship between obesity and risk of breast cancer is complex. In a large prospective study in the United States, mortality from breast cancer was about 50% higher among women who were more than 40% above average weight for their height than among women of average weight<sup>125</sup>. This may partly be because tumours are diagnosed later among obese women<sup>122</sup>, rather than because of an aetiological role of obesity. In studies that considered the incidence of breast cancer rather than mortality, a distinct difference has been found between pre- and post-menopausal women. Before menopause, greater relative weight is associated with a reduced risk of breast cancer<sup>122,126</sup>; rates among those in the heaviest 20% are about 40% lower than among the thinnest. Among post-menopausal women, positive associations with relative weight have been seen in several studies<sup>127-131</sup>, but these have been generally weak, without a clear dose-response relationship, and in some studies no association was observed<sup>126,132</sup>.

A weak positive association was seen between relative weight and mortality from colon cancer in men, but not women, in one large prospective study<sup>125</sup>. However, in some case-control<sup>68</sup> and prospective cohort<sup>133,134</sup> studies, relative weight had little association with incidence of colon cancer.

### Contrasts between breast and colon cancers

Although the striking international correlations of both breast and colon cancer rates with indices of affluence suggest common aetiological factors, other evidence indicates important differences in aetiology or the period of life during which the factors act. For example in the United States, Japanese immigrants have rates of colon cancer similar to those of the caucasian population, whereas rates of breast cancer take several generations to approach those of the resident population<sup>135,136</sup>. Rates of breast cancer among Seventh-Day Adventists are similar to those in the general population, but rates of colon cancer are about 40% lower<sup>58</sup>.

The relationship between changes in diet and rates of mortality from breast and colon cancer are uniquely illustrated in Japan, where there has been a dramatic change in diet since World War II (Fig. 3). Between 1955 and 1975, fat intake increased from about 10% to about 25% of total energy intake. This has been accompanied by a striking rise in mortality from colon cancer but only a small change in breast cancer mortality. These data do not necessarily indicate that the fat composition of the diet caused the rapid rise in colon cancer, but they do suggest strongly that environmental changes will more rapidly influence rates of colon than breast cancer and that large changes in fat intake will be accompanied by changes in rates of breast cancer that are, at most, modest or substantially delayed.

It is useful to compare case-control and prospective cohort studies of colon and breast cancer conducted by the same investigators using similar methods, because the results are relatively unobscured by the differences typically found in study populations and research designs. Such pairs of studies have been conducted in upstate New York<sup>96,101</sup>, Greece<sup>93,100</sup>, Canada<sup>68,40</sup>, Californian Seventh-Day Adventists<sup>41</sup>, Australia<sup>69,37</sup> and nurses in the United States<sup>47,79</sup>. Except in the upstate New York study, clear associations were seen between fat or meat intake and risk of colon cancer, but not of breast cancer, in each pair of analyses. These comparisons provide further evidence that the failure to find associations between diet and breast cancer in case-control and cohort studies is not simply due to lack of heterogeneity in diet or imprecise methods of assessing diet.

FIG. 2 Risk of breast cancer related to level of alcohol consumption, with 95% confidence intervals, based on pooled estimates from five prospective studies<sup>102</sup>. In women consuming 12 g of alcohol per day, about one standard drink of beer, wine or liquor, the risk of breast cancer was ~40% higher than in non-drinkers. The risk for 24 g per day rose to ~70% and for 36 g per day to ~100% compared with non-drinking women. (From ref. 111, with permission of the American Medical Association.)

## Prospects

In spite of strong evidence that non-genetic factors account for the high rates of breast and colon cancer in industrialized countries, few specific aetiological factors are well established that offer the potential for prevention. Among the associations considered here, drinking alcohol and the risk of breast cancer is the relationship most strongly supported by epidemiological findings, but it is not certain whether this represents cause and effect. The benefits of reducing alcohol intake remain unclear because any influence on breast cancer risk may be limited to young adulthood. In adult women, a modest reduction in dietary fat and avoiding obesity seem likely to have little, if any, impact on reducing the risk of breast cancer. On the contrary, accumulating data indicate that being thin before menopause may actually increase the risk of breast cancer.

Several lines of evidence indicate that risk of colon cancer may be more responsive than breast cancer to changes in diet. Associations between dietary fat and colon cancer have been found in several studies; whether this represents a causal effect of the fat composition of the diet remains unproven and the type of fat rather than its total amount may be most important. Inverse associations have been found repeatedly between consumption of fruits and vegetables and the risk of colon cancer. The process of translating these epidemiological findings into public recommendations has taken an interesting turn: data on fruit and vegetable consumption have been used to compute fibre intake and, based on the resulting inverse associations with fibre intake, recommendations have been made to consume more whole-grain cereal, even though there is a consistent lack of evidence for a protective role of cereal fibre in epidemiological studies.

Except for limiting alcohol intake, which could at most only modestly decrease the incidence of breast cancer, prospects for prevention of breast cancer seem limited in the near future. The potential for preventing colon cancer by changes in diet seems greater, but exactly how needs to be more clearly defined. Increasing the intake of fruits and vegetables seems promising and reducing consumption of animal fats may prove to be effective. Large prospective studies of diet that are now under-

way or planned, together with randomized trials of dietary factors in relation to recurrence of colon polyps that are now in progress, will provide much additional information about the effects of specific foods and nutrients. □

FIG. 3 Relative changes in fat intake and age-adjusted rates of mortality from breast and colon cancer in Japan between 1955 and 1985. During this period, fat intake increased by ~180% (from ~10-25% of energy intake) whereas total energy intake remained nearly constant. By 1984, age-adjusted mortality from breast cancer had increased ~45%, whereas mortality from colon cancer among women increased by 130%, an increase proportional to increased fat intake with a lag of ~15 years. Much of the modest increase in breast cancer mortality is probably a result of marked changes in reproductive patterns; for example, the percentage of women having their first child before the age of 19 decreased from 13 to 4% between 1950 and 1975<sup>10</sup>. Although data for incidence of breast cancer are available for a more limited period, they also indicate only a slow increase over time<sup>135</sup>. Absolute levels in 1955 were 20.3 g per day of fat per capita, 1.9 colon cancer deaths per 10<sup>5</sup> person-years, and 3.3 breast cancer deaths per 10<sup>5</sup> person-years. (Based on data from Health and Welfare Statistics Association, Japan<sup>11</sup>.)

## ARTICLES

# The tails of ubiquitin precursors are ribosomal proteins whose fusion to ubiquitin facilitates ribosome biogenesis

Daniel Finley\*, Bonnie Bartel & Alexander Varshavsky

Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Three of the four yeast ubiquitin genes encode hybrid proteins which are cleaved to yield ubiquitin and previously unidentified ribosomal proteins. The transient association between ubiquitin and these proteins promotes their incorporation into nascent ribosomes and is required for efficient ribosome biogenesis. These results suggest a novel 'chaperone' function for ubiquitin, in which its covalent association with other proteins promotes the formation of specific cellular structures.

THE covalent ligation of ubiquitin to various acceptor proteins in eukaryotic cells participates in or regulates a number of cellular processes, such as selective protein degradation<sup>1-3</sup>, DNA repair<sup>4</sup>, progression through the cell cycle<sup>2,5,6</sup> and a variety of stress responses<sup>7-11</sup>. A major function of ubiquitin is to mark

proteins destined for selective elimination<sup>12-14</sup>. An alternative role for ubiquitin has also been suggested<sup>15</sup>, in which it reversibly joins to an acceptor protein to modulate protein function without metabolically destabilizing the acceptor protein. *In vivo* acceptors of ubiquitin include histones H2A and H2B<sup>16</sup>, actin<sup>17</sup>, the lymphocyte homing receptor<sup>18</sup>, the platelet-derived growth factor receptor<sup>19</sup>, the growth hormone receptor<sup>20</sup> and the intracellular neurofibrillary tangles in neurodegenerative diseases such as Alzheimer's<sup>21-22</sup>.

The conjugation of ubiquitin to other proteins involves the formation of an isopeptide bond between the C-terminal glycine residue of ubiquitin and the  $\epsilon$ -amino group of a lysine residue in the acceptor protein<sup>1,12</sup>. In the yeast *Saccharomyces cerevisiae*, the six or more enzymes that catalyse such reactions<sup>15</sup> include the products of the genes *RAD6*, which is required for DNA repair<sup>4</sup> and *CDC34*, which is required for the transition from the G1 to the S phase of the cell cycle<sup>5</sup>. Ubiquitinated proteins often contain single ubiquitin moieties linked to one or more of the acceptor protein's lysine residues<sup>12,16,17,23</sup>. Alternatively, several ubiquitin moieties can be attached sequentially to an acceptor protein to form a chain of branched ubiquitin-ubiquitin conjugates in which the C-terminal Gly 76 of one ubiquitin is

\* Present address: Department of Cellular and Molecular Physiology, Harvard Medical School, Boston, Massachusetts 02115, USA.

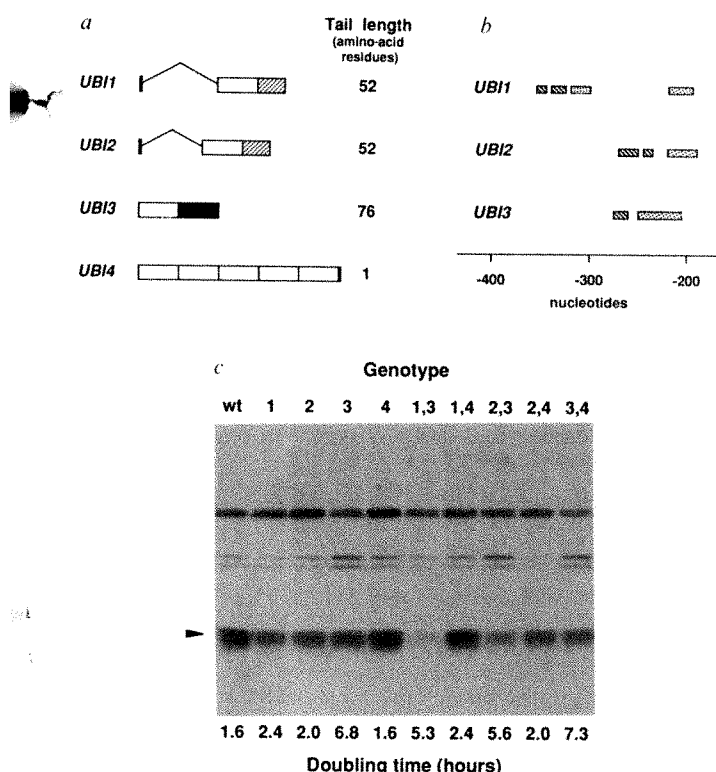

FIG. 1. *S. cerevisiae* ubiquitin genes and ubiquitin mutants. **a**, Organization of yeast ubiquitin genes. Open blocks represent the 228-base pair (bp) ubiquitin-coding repeats. Striped and shaded blocks represent tail-coding elements. *UBI1* and *UBI2* contain identically positioned, mostly nonhomologous introns within their ubiquitin-coding elements<sup>24</sup>. **b**, Putative upstream activation (UAS) sites of *UBI1-UBI3* genes. Positions are relative to the ATG start codon in each gene. Striped blocks represent near-matches (11–14 out of 15) to the consensus sequence of UAS sites within genes for ribosomal proteins<sup>30</sup>. Stippled blocks represent T-rich stretches often found downstream of such UAS sites<sup>30</sup>. **c**, Immunoblot analysis of intracellular ubiquitin levels and doubling times of yeast strains bearing deletions of various ubiquitin genes. Wild-type lane is on the left; other lanes are numbered at the top according to the ubiquitin gene or genes deleted in the corresponding strain (for example, lane 1, *ubi1* strain). The ubiquitin band is indicated by an arrow. The doubling time of each strain at 30 °C in YPD, a rich medium<sup>46</sup>, is indicated underneath; the same growth conditions were used in the immunoblotting experiment. The bands of high molecular weight presumably correspond to ubiquitin-protein conjugates.

**METHODS.** Exponentially growing cells were centrifuged at 5,000 *g* for 5 min at 4 °C, resuspended in 30 mM Tris-HCl (pH 6.8), 1 mM MgCl<sub>2</sub>, centrifuged again, and resuspended in a buffer containing 30 mM Tris-HCl (pH 6.8), 1 mM MgCl<sub>2</sub>, 2 mM *N*-ethylmaleimide, 10 µg ml<sup>-1</sup> antipain, 10 µg ml<sup>-1</sup> leupeptin, 10 µg ml<sup>-1</sup> aprotinin, 10 µg ml<sup>-1</sup> chymostatin and 10 µg ml<sup>-1</sup> pepstatin (Sigma). Cells were lysed by vortexing in the presence of glass beads, and the extracts were centrifuged at 12,000 *g* for 10 min. Protein (150 µg) was loaded onto each lane of an 18% polyacrylamide-SDS gel. Fractionated proteins were then electroblotted onto PVDF membranes (Millipore) for 20 min at 13 V cm<sup>-1</sup> (under these conditions, the transfer of high molecular weight proteins is not complete). Filters were probed with an antibody to ubiquitin<sup>21</sup>, followed by <sup>125</sup>I-labelled Protein A (ICN Radiochemicals) using standard techniques<sup>8</sup>. The filter-bound <sup>125</sup>I-Protein A was detected by autoradiography. Doubling times were determined by monitoring the absorbance at 600 nm of exponentially growing liquid cultures. All strains analysed were *MATα*. All strains used in this work are congeneric, being derived from DF5 (*MATα/MATα*, *trp1-1* (*am*)/*trp1-1* (*am*), *ura3-52/ura3-52*, *his3-Δ200/his3-Δ200*, *leu2-3,2-112/leu2-3,2-112*, *lys2-801/lys2-801*), a previously described homozygous diploid<sup>8</sup>. Precise chromosomal deletions were constructed essentially as described<sup>8</sup>, except that in the case of the *UBI2* *in vitro* deletion, we used restriction endonucleases rather than an oligonucleotide. A 1.6 kilobase (kb) genomic *HincII* fragment containing the *UBI2* gene<sup>24</sup> was subcloned into pUC13 (ref. 48), and the resulting plasmid was digested with *HindIII* and *ClaI*, deleting all but 8 bp of the *UBI2* coding sequence and no noncoding sequence. Subsequent steps were as described<sup>8</sup>. The deletion-disruption mutation *ubi1* was marked with the *TRP1* gene, whereas *ubi2* was marked with *URA3* and *ubi3* with *HIS3*.

joined to the internal Lys 48 of an adjacent ubiquitin<sup>23</sup>. The attachment of such a multi-ubiquitin chain to the proteolytic substrate is apparently essential for the degradation of a variety of proteins<sup>23</sup>.

Unlike the branched ubiquitin-protein conjugates, which are formed post-translationally, linear ubiquitin adducts are formed as the translational products of natural gene fusions<sup>7,24,25</sup>. Thus, in *S. cerevisiae* for example, ubiquitin is generated exclusively by proteolytic processing of precursors in which ubiquitin is joined either to itself, as in the linear polyubiquitin protein *UBI4*, or to unrelated 'tail' amino-acid sequences, as in the hybrid proteins *UBI1*, *UBI2* and *UBI3* (Fig. 1a). In growing yeast cells, most ubiquitin is generated from the *UBI1-UBI3* hybrid proteins<sup>8</sup>. The polyubiquitin (*UBI4*) gene is dispensable in growing cells but becomes essential (as the main supplier of ubiquitin) during stress<sup>8</sup>.

The tail amino-acid sequences of the ubiquitin precursors are highly conserved between yeast and mammals<sup>7,24,25</sup>, suggesting that they function similarly in all eukaryotes. The yeast *UBI1* and *UBI2* genes encode identical 52-residue tails, whereas *UBI3* encodes a 76-residue tail with little amino-acid sequence similarity to the tails of the *UBI1* and *UBI2* proteins<sup>24</sup> (Fig. 1a). Both the *UBI1/UBI2* and *UBI3* tails are highly basic however, and contain cysteine-rich, putative zinc-binding domains, suggesting that these proteins may bind nucleic acids<sup>24</sup>.

We report here that these tails are ribosomal proteins whose fusion to ubiquitin facilitates ribosome biogenesis. These and related results suggest a novel, 'chaperone' function for ubiquitin, in which its covalent association with other proteins can promote the formation of specific cellular structures.

### Deletion analysis of the *UBI1-UBI3* genes

To investigate the functions of the ubiquitin-hybrid genes, we precisely deleted the coding sequences of these genes from the *S. cerevisiae* genome (see Fig. 1 legend). Unlike the deletion of *UBI4*<sup>8</sup>, deletions of the ubiquitin-hybrid genes resulted in slow growth phenotypes, with the *ubi3* deletion having a much more severe effect than the *ubi1* or *ubi2* deletions (Fig. 1c). The phenotypes of the *ubi1* and *ubi2* single mutants can be viewed essentially as gene dosage effects, because *UBI1* and *UBI2* encode identical proteins<sup>24</sup> and because the *UBI2* gene, carried on a centromere-containing (*CEN*) plasmid, fully complemented the growth defect of the *ubi1* mutant (data not shown). The *ubi1 ubi2* double mutant is not viable, as indicated by our inability to recover *ubi1 ubi2* meiotic segregants upon sporulation of a *ubi1/+*, *ubi2/+* diploid, and by the fact that a yeast plasmid carrying the *UBI2* gene and an origin of replication, but lacking a *CEN* element was fully stabilized against mitotic loss in a *ubi1 ubi2* genetic background (data not shown). Thus, *UBI1* and *UBI2* encode an essential protein and seem to be functionally interchangeable genes.

The relative contributions of *UBI1-UBI4* to steady-state levels of free ubiquitin were assessed by immunoblotting. Deletion of any one of the four yeast ubiquitin genes resulted in, at most, a slight decrease in the level of free ubiquitin (Fig. 1c). Strikingly, there was no correlation between growth rates of the various deletion mutants and their levels of free ubiquitin (Fig. 1c). The growth defects of the *ubi1*, *ubi2* and *ubi3* deletion mutants must therefore be due, at least in part, to either the absence or decrease in concentration of specific tail components of the *UBI1-UBI3* proteins.

To further dissect the contributions of ubiquitin and the tails to the functions of the ubiquitin-hybrid genes, genetic elements encoding the tail and ubiquitin moieties were separated from each other in plasmid constructs, introduced into the mutant strains described above, and tested for their ability to complement the cognate deletion mutations (Fig. 2). Oligonucleotide-directed mutagenesis was used to construct a plasmid in which the entire ubiquitin-coding component of *UBI3*, except for its initiator ATG codon, had been deleted. This plasmid, which

retained the flanking regions of the *UBI3* gene, but expressed the *UBI3* tail in a ubiquitin-free form, fully complemented the growth deficiency of the *ubi3* deletion mutant. Other *ubi3* phenotypes, such as hypersensitivity to nitrogen starvation, defective processing of RNA precursors (see below) and the abnormally large size of *ubi3* cells, were also complemented by the *UBI3* tail-expressing plasmid. Although in these experiments the *UBI3* tail gene was carried on a low copy number *CEN* plasmid, the observed full complementation of the *ubi3* phenotype depended on a moderate amplification of the plasmid copy number (see below). In contrast to the *UBI3* tail, free ubiquitin, when expressed from the *UBI3* promoter, did not complement any of the *ubi3* phenotypes significantly. A plasmid, pUb39, which expressed free ubiquitin from the *CUP1* promoter<sup>26</sup> at a rate comparable to that of *UBI1-UBI4* combined, also failed to complement *ubi3* (Fig. 2).

In analogous experiments with *UBI1*, we expressed ubiquitin and the *UBI1* tail separately using heterologous promoters, as plasmids carrying the *UBI1* promoter sequence were unstable in yeast. Expression of the free *UBI1* tail from the strong *GPD* promoter<sup>27</sup> complemented the lethal phenotype of the *ubi1 ubi2* double deletion and supported wild-type growth rates in this genetic background (Fig. 2). These results indicated that the *UBI1* and *UBI2* tails are essential proteins and can function without an N-terminal ubiquitin moiety. In a complementary experiment, the free ubiquitin-expressing plasmid pUb39 failed to rescue the viability (ability to germinate) of *ubi1 ubi2* spores (Fig. 2).

FIG. 2 Summary of plasmid-based genetic complementation tests. Plasmids were transformed as described<sup>46</sup> into singly or multiply heterozygous diploids of the appropriate genotype. Transformants were sporulated and appropriate meiotic products of both mating types were tested for viability and growth rates. ND, not determined.

**METHODS.** Growth was assayed in media selective for the plasmid-borne selectable marker, wild-type growth being taken as that of a chromosomally wild-type strain transformed with the parental plasmid lacking ubiquitin genes and their derivatives. To construct pUb94, the ubiquitin-coding element of *UBI1* was deleted (except for its start codon) from a *UBI1*-containing DNA fragment, as described<sup>47</sup> (see also Fig. 1 legend). A 340-bp *HinfI* fragment containing the tail-coding element of *UBI1* was ligated to *Bam*H1 linkers and subcloned into *Bam*H1-digested pGPD(G)-2 (ref. 27; pGPD(G)-2 has a UAS<sup>gal</sup>-containing DNA fragment inserted into the *SalI* site of pGPD(s)-2; G. Bitter, personal communication) to yield pUb92. In this way the *GPD* promoter was positioned in place of the *UBI1* promoter. The expression cassette thus constructed was subcloned into the *SmaI* site of YE351 (ref. 49), yielding pUb94. pUb36 is a YCp50-based<sup>50</sup> vector containing a *UBI3* tail-coding element (the ubiquitin-coding element is deleted), about 700 bp of 5' noncoding sequence from the *UBI3* gene, and about 400 bp of 3' noncoding sequence. pUb95 was constructed by subcloning the pUb36 insert into the unique *XbaI* site of pUb94. pUb39 is identical to YE46 (ref. 26) except that it carries the *LYS2* rather than *TRP1* selectable marker. pUb35 is identical to pUb36 except that its insert contains the *UBI3* ubiquitin-coding element (the tail-coding element is deleted). Because the expression of the *UBI1* tail from the plasmids pUb94 and pUb95 is galactose-dependent, glucose was replaced in the medium by 2% galactose, 2% glycerol, 2% ethanol and 40  $\mu\text{g ml}^{-1}$  aspartic acid<sup>51</sup> when these plasmids were assayed for complementation.

These results indicate that the tails of ubiquitin-hybrid proteins have growth-related functions and that location of the tails within ubiquitin-hybrid proteins is not strictly essential for tail function. It has been proposed that the ubiquitin-tail fusion arrangement may instead be required for ubiquitin function<sup>28</sup>; the tails, by virtue of their apparent nuclear targeting signals<sup>24,28</sup>, might mediate transport of ubiquitin to the nucleus. To test this possibility, a strain entirely lacking ubiquitin-hybrid proteins was generated. We constructed a plasmid, pUb95, that expressed both *UBI1* and *UBI3* tails in a ubiquitin-free form and transformed it into a *ubi1/+*, *ubi2/+*, *ubi3/+* diploid, which was sporulated and subjected to tetrad analysis (Fig. 2). In the presence of the free tail-expressing plasmid, *ubi1 ubi2 ubi3* meiotic products could be recovered as viable cells, indicating that linkage of the tails to ubiquitin within the ubiquitin-hybrid proteins does not support an essential function of ubiquitin. The polyubiquitin gene, *UBI4*, the only ubiquitin gene that remained in the *ubi1 ubi2 ubi3* mutants, was strongly induced in this genetic background (unpublished data).

### Deficiency of ribosomal subunits

In the course of a northern hybridization experiment, RNA preparations from the various *ubi1-ubi3* mutants were analysed electrophoretically. This revealed a strikingly substoichiometric ratio of 18S to 25S rRNA in the *ubi3* mutants (Fig. 3a). The 18S and 25S rRNAs reside within the small (40S) and large (60S) ribosomal subunits, respectively, and their normal 1:1 stoichiometry is maintained partly because they are derived from a single precursor transcript<sup>29,30</sup>.

To test whether the deficiency of 18S rRNA in the *ubi3* mutants was accompanied by a deficiency of small ribosomal subunits, we prepared extracts from *ubi3* and wild-type cells under conditions which dissociate translating polyribosomes<sup>31</sup>. The extracts were sedimented through 15–30% sucrose gradients at low ionic strength, which promotes the association of large and small ribosomal subunits into 80S ribosomes (monosomes). The main sedimentation peak in the wild-type extract was monosomal (Fig. 4a). In contrast, the main peak in the *ubi3* extract was composed of free 60S subunits, and the monosome peak was greatly reduced. These results indicate that the *ubi3* mutants contain substoichiometric quantities of small ribosomal subunits.

To determine whether the *ubi3* mutant was defective in the formation (rather than metabolic stability) of 40S ribosomal subunits, we examined the processing of pre-rRNA in mutant and wild-type cells. Pre-rRNA processing was monitored using a pulse-chase procedure, followed by agarose gel electrophoresis and fluorography. The results are shown in Fig. 3c and d, together with a diagram of the pre-rRNA processing pathway (Fig. 3b). After a 6-min pulse, the predominantly labelled species are the 27S and 20S RNAs, which are the immediate precursors of the mature 25S and 18S rRNAs, respectively. In wild-type cells at 30 °C, these intermediate species are processed to completion within 30 min, whereas in the *ubi3* cells the rate at which the 18S rRNA is generated from the 20S pre-rRNA is dramatically reduced, and the bulk of the 20S pre-rRNA is ultimately degraded rather than processed. In contrast, the conversion of the 27S precursor to the 25S rRNA (residing in the large ribosomal subunit) is normal in the *ubi3* mutant (Fig. 3d). The 20S pre-rRNA processing defect cannot be accounted for by a defect in its transport to the cytoplasm (data not shown), where the 20S pre-rRNA is normally converted to 18S rRNA<sup>29</sup>. Thus, a specific pre-rRNA processing defect explains the aberrant stoichiometry of rRNA in the *ubi3* mutant and accounts, at least in part, for its growth defect.

Remarkably, both the *ubi1 ubi3* and *ubi2 ubi3* double mutants grow faster than the *ubi3* single mutant, despite their relatively low free ubiquitin levels (Fig. 1c). This is particularly striking as the *ubi1* and *ubi2* single mutants grow more slowly than wild-type cells (Fig. 1c). Thus, *ubi1* and *ubi2* are both weak

suppressors of *ubi3*. Figure 3a shows that *ubi1* and *ubi2* also partially restore the stoichiometry of 18S rRNA to 25S rRNA in the *ubi3* genetic background. This result indicates that *UBI1* and *UBI2* are, like *UBI3*, involved in some aspect of ribosome assembly or turnover. Although the ratio of 18S rRNA to 25S rRNA, as estimated from gel electrophoretic patterns (Fig. 3a), is not noticeably abnormal in either *ubi1* and *ubi2* mutants, a more sensitive assay, namely sucrose gradient sedimentation, revealed a deficiency of 60S subunits in the *ubi1* mutant, in contrast to the *ubi3* mutant which was deficient in 40S subunits (Fig. 4b). A slight reduction in the monosome level (relative to total RNA in the extract) was also apparent in the *ubi1* cells (Fig. 4b; compare the 80S peak to the peak at the top of the gradient). Although the 60S subunit deficiency of *ubi1* cells is moderate, it is presumably sufficient to account for the mild

growth defect of these cells (Fig. 1c), which still express a protein identical to *UBI1* from the *UBI2* gene.

The partial suppression of the *ubi3* growth defect by the *ubi1* and *ubi2* mutations (Fig. 1c) may result from their lowering of 60S subunit levels and thus partially alleviating the relative deficiency of 40S subunits, perhaps without significantly affecting the absolute levels of 40S subunits. Although the coupling of 40S and 60S subunits within the ribosome only occurs after the 40S subunit associates with mRNA, the two subunits have significant residual affinity for each other in the absence of mRNA<sup>32</sup>. As a result, the abnormally high level of free 60S subunits in the *ubi3* mutant (Fig. 4a) may lead to partial sequestration of 40S subunits, thereby further decreasing the concentration of free 40S subunits available for translation in *ubi3* cells. This effect, analogous to the 'squelching' effect described for transcriptional regulators<sup>33</sup>, should become weaker after a decrease in the level of 60S subunits, possibly accounting for the suppressive effect of the *ubi1* and *ubi2* mutations in the *ubi3* genetic background (Figs 1c and 3). As the growth of the *ubi3* mutant is cold-sensitive (relative to wild-type), whereas the ratio of 18S rRNA to 25S rRNA in *ubi3* cells does not change at low temperatures (data not shown), the hypothetical sequestration effect may decrease at higher temperatures. Alternatively, those few 40S ribosomal subunits which do form in the absence of the *UBI3* tail may be intrinsically

FIG. 3 Defective pre-rRNA processing and reduced levels of 18S rRNA in the *ubi3* mutant. *a*, RNA was prepared from mutant and wild-type cells grown in YPD, electrophoresed on a 1% agarose gel in the presence of ethidium bromide and photographed under ultraviolet light. Lanes are numbered according to the ubiquitin gene or genes deleted in the corresponding strain. *b*, Schematic representation of the pathway of pre-rRNA processing in *S. cerevisiae*. 35S RNA is the primary transcript. *c*, *d*, Pulse-chase analysis of pre-rRNA processing in wild-type and *ubi3* deletion strains. rRNA precursors in exponentially growing yeast cells were labelled (in minimal medium supplemented with auxotrophic nutrients<sup>46</sup>) with [methyl-<sup>3</sup>H]methionine (Amersham, 80 Ci mmol<sup>-1</sup>) for 6 min at 23 °C. ([methyl-<sup>3</sup>H] methionine donates methyl groups to newly synthesized pre-rRNA<sup>29</sup> via the general methyl donor *S*-adenosylmethionine.) Unlabelled methionine (1 mg ml<sup>-1</sup>) was added to initiate the chase incubation, and RNA was prepared from the cells at the times indicated. RNA was electrophoresed on a 1% agarose gel and visualized by fluorography. Molecular weights are shown on the left, in thousands. METHODS. RNA was prepared from exponentially growing cells as described previously<sup>52</sup>, except that 0.2% diethylpyrocarbonate was added to the lysis buffer and SDS was omitted. RNA (10 µg per lane) was electrophoresed on formaldehyde-containing gels as described previously<sup>47</sup>, except that formaldehyde was used at 0.2 M, and iodoacetamide (10 mM) and ethidium bromide (0.5 µg ml<sup>-1</sup>) were also added to the gel (B. Seed, personal communication). All strains analysed were *MATα*.

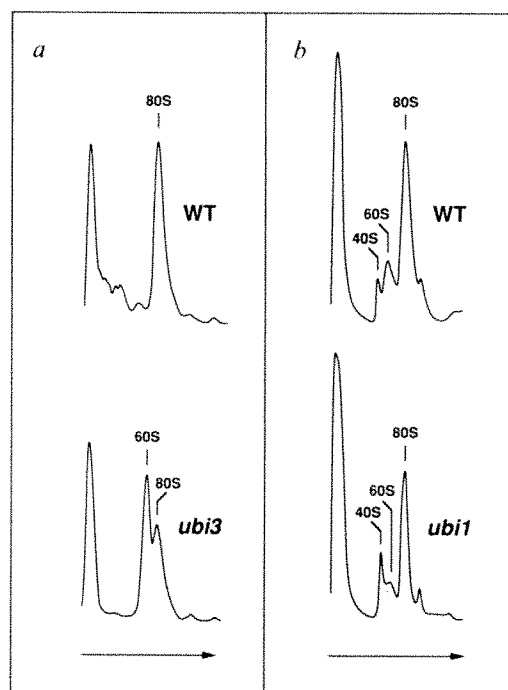

FIG. 4 Aberrant stoichiometries of ribosomal subunits in *ubi1* and *ubi3* mutants. Sedimentation analysis of subunits present in cytoplasmic extracts from spheroplasts of either (a) wild-type and *ubi3* strains, or (b) wild-type and *ubi1* strains. Direction of sedimentation is indicated by an arrow. METHODS. Spheroplasts were prepared from cells grown in YPD by digestion with zymolyase as described previously<sup>31</sup>. After allowing the spheroplasts to recover<sup>31</sup>, sodium azide was added, and the culture was brought to 8 °C for 5 min to induce polyribosome 'run off'<sup>31</sup>. Spheroplasts were then lysed as described<sup>31</sup>, except that heparin (0.2 mg ml<sup>-1</sup>) was added to the lysis buffer<sup>53</sup>. Extracts were centrifuged at 20,000 *g* for 15 min. In *b*, the ionic strength of the extract was then reduced by diluting it threefold into gradient buffer. Supernatants were loaded onto 15–30% linear sucrose gradients prepared to 50 mM Tris-HCl (pH 7.4), 50 mM KCl, 5 mM MgCl<sub>2</sub>, 2 mM dithiothreitol and centrifuged at either 39,000 r.p.m. for 3 h (a) or 35,000 r.p.m. for 5 h (b) in an SW41 rotor (Beckman) at 5 °C. Gradients were fractionated by upward displacement in an ISCO gradient fractionator equipped with a UV monitor. Peak assignments are based on electrophoretic analysis of RNA prepared from appropriate gradient fractions. All strains analysed were *MATα*.

cold-sensitive, presumably because they lack the UBI3 tail (see below).

### The tails are ribosomal proteins

The above results, which indicate that the UBI3 tail participates in ribosome biogenesis, suggested that this tail was either a component of the pre-rRNA processing apparatus, which seems to include a variety of small nuclear ribonucleoprotein particles<sup>34</sup>, or a ribosomal protein whose incorporation into the nascent ribosome facilitates recognition of the 20S pre-rRNA by specific processing factors. To distinguish between these possibilities, we added an immunological marker to the C-terminus of the UBI3 protein by fusing the *UBI3* gene with a sequence encoding a 12-residue epitope from the human *c-myc* gene product<sup>35</sup>. The resulting *UBI3-myc* gene fully complemented the growth defect of the chromosomal *ubi3* deletion, indicating that the C-terminal Myc peptide did not obstruct the activity of the UBI3 protein. Whole-cell extracts of wild-type (*UBI3*) cells and of *UBI3-myc* cells carrying a chromosomal deletion of *ubi3* were fractionated by SDS-PAGE, transferred onto filters and probed with a monoclonal antibody to the Myc peptide. A single band was observed in immunoblots of *UBI3-myc* cells, whereas extracts from wild-type cells were essentially free of antibody-binding species (Fig. 5a, lane W). The immunoreactive protein is apparently the deubiquitinated form of UBI3-Myc, as it is not recognized by antibodies to ubiquitin, and its apparent molecular weight is considerably less than that of UBI3-Myc produced in *Escherichia coli* (Fig. 5a). This, with the data of Fig. 2, suggests that the UBI3 hybrid protein is efficiently processed (deubiquitinated) *in vivo*. Rapid *in vivo* deubiquitination in eukaryotic cells (but not in bacteria) is also characteristic of engineered ubiquitin fusions such as ubiquitin- $\beta$ -galactosidase<sup>36</sup>.

Extracts from wild-type and *UBI3-myc* cells were analysed on sucrose gradients under optimal conditions for the resolution of polyribosomes (Fig. 5a). The proteins of the monosome and polyribosome peaks were fractionated by SDS-PAGE, transferred onto filters and probed with the anti-Myc antibody. The Myc-tagged UBI3 tail protein was found primarily within rapidly sedimenting structures, and co-sedimented with both 80S monosomes and the broadly distributed polyribosomes (Fig. 5a). A second extract was prepared from *UBI3-myc* cells under conditions that dissociate polyribosomes, and centrifuged in the presence of a high ionic strength buffer, which dissociates monosomes into free subunits. Under these conditions the UBI3 tail co-sedimented with the 40S ribosomal subunit (Fig. 5b). Taken together, these data indicate that the UBI3 tail is a component of the small subunit of the ribosome. The UBI3 tail does not seem to be a processing or assembly factor that is transiently associated with nascent 40S subunits because it is also present within translationally active ribosomes. The association of the UBI3 tail with the 40S subunit persists under high salt conditions (0.5 M KCl), suggesting that the UBI3 tail is tightly associated with mature ribosomes.

To localize the UBI1 tail protein, we again used the Myc tagging method. A *UBI1 tail-myc* gene in which the Myc sequence was positioned upstream of the tail-coding sequence in place of the ubiquitin-coding sequence, rescued the viability of *ubi1 ubi2* mutants and restored their growth rates to near wild-type levels. Extracts from *UBI1 tail-myc* cells were fractionated on sucrose gradients optimized for the analysis of either polyribosomes or ribosomal subunits, as described above for *UBI3-myc*. On the polyribosome gradient, the UBI1 tail co-sedimented with 80S monosomes and polyribosomes (Fig. 5c), whereas on the ribosomal subunit gradient the UBI1 tail co-sedimented with the 60S subunit (Fig. 5d). Thus, like the UBI3 tail, the UBI1 tail is tightly associated with mature, translationally active ribosomes. We conclude that the UBI3 tail, and the identical UBI1 and UBI2 tails, are ribosomal proteins which reside in the small and large subunits, respectively. The main

structural motifs of the UBI1-UBI3 proteins, their putative zinc fingers<sup>24</sup>, are presumably involved in binding rRNA.

Although both UBI1 tail-Myc and UBI3-Myc were found in ribosomes, their localization to distinct ribosomal subunits precludes the possibility that these associations were mediated artefactually by the Myc peptide. Moreover, the human homologue of the UBI3 tail protein has independently been localized to the small ribosomal subunit<sup>37</sup>. Our data do not exclude the possibility that a fraction of the UBI1 and UBI2 tails are present within yeast ribosomes in an unprocessed, ubiquitin-containing form. The presence of significant levels of free ubiquitin in *ubi3 ubi4* mutants (Fig. 1c) does indicate, however, that the UBI1 and UBI2 gene products can be deubiquitinated; furthermore, the full complementing activity of the free UBI1 tail indicates that ribosomes containing the free UBI1 tail are functionally indistinguishable from wild-type.

Examination of the previously determined<sup>24</sup> nucleotide sequences upstream of the *UBI1*, *UBI2* and *UBI3* genes revealed near-matches to the consensus sequence<sup>30</sup> of upstream activation sites (UAS) within genes for ribosomal proteins (Fig. 1b). (Such UAS<sup>TP8</sup> sites have also been found within a few genes encoding non-ribosomal proteins<sup>30</sup>.) The *UBI1*, *UBI2* and *UBI3* promoter regions also contain T-rich stretches which represent a second sequence motif characteristic of promoters of ribosomal protein genes<sup>30</sup> (Fig. 1b). In *UBI1-UBI3*, the positioning of these UAS and T-rich sequences with respect to each other and to sites of translational initiation, is similar to that of known ribosomal protein genes and consistent with the proposed function of these sequences in transcriptional regulation. With the exception of genes for ribosomal proteins, few yeast genes contain introns; their presence within the *UBI1* and *UBI2* genes (Fig. 1a) further indicates that the sequence features of *UBI1-UBI3* are typical of ribosomal protein genes.

### Ubiquitin and ribosome biogenesis

The tandem arrangement of ubiquitin and specific ribosomal proteins (tails) within proteolytically processed precursors has been conserved throughout the evolution of eukaryotes<sup>7,25</sup>. Nevertheless, expression of the tails in a ubiquitin-free form can fully complement chromosomal mutations in which the corresponding ubiquitin-tail gene is entirely deleted (see above). To test further for a function of the cotranslational synthesis of ubiquitin and the tail proteins, we integrated the free tail-expressing derivative of the *ubi3* gene (*ubi3 $\Delta$ ub*) into its natural chromosomal locus. The complete deletion mutant, *ubi3*, which grows slowly (Fig. 1c), was transformed with linear DNA fragments carrying either the ubiquitin deletion mutation *ubi3 $\Delta$ ub* or the wild-type *UBI3* gene and growth revertants were selected. Growth revertants resulting from transformation with *ubi3 $\Delta$ ub* DNA were predominantly of two classes: those growing at wild-type rates (1.6-h doubling time) and those in which the *ubi3* growth defect had been only partially reverted (3-h doubling time, compared with the 6.8-h doubling time of the *ubi3* mutant). Southern hybridization analysis (data not shown) indicated that in all seven of the revertants with wild-type growth rates, the *ubi3* mutation had been replaced by multiple tandem insertions of *ubi3 $\Delta$ ub* DNA, whereas in all 12 partial growth revertants analysed, *ubi3* had been replaced with a single, properly integrated *ubi3 $\Delta$ ub* sequence (see Fig. 6a for a comparison of growth rates; we refer to the integrated, single-copy *ubi3 $\Delta$ ub* allele as *ubi3 $\Delta$ ub-1*, and to the integrated multiple-copy allele taken for analysis as *ubi3 $\Delta$ ub-2*). In contrast, single-copy integration of wild-type (*UBI3*) DNA resulted in complete reversion of the *ubi3* growth defect (Fig. 6a). These results, which strongly suggested that the *ubi3 $\Delta$ ub* allele can fully complement *ubi3* only when present in multiple copies, were confirmed by showing that in a *ubi3* genetic background, the copy number of CEN plasmids carrying the *ubi3 $\Delta$ ub* allele was several times higher than that of CEN plasmids carrying the *UBI3* allele, whereas in a wild-type genetic background such

plasmids had equivalent copy numbers (data not shown). Thus, regardless of whether the free tail-expressing (*ubi3 $\Delta$ ub*) allele is carried on a *CEN* plasmid or integrated into the chromosome, full complementation of the *ubi3* phenotype requires approximately three to fourfold amplification of the *ubi3 $\Delta$ ub* copy number.

To determine the stoichiometry of 18S to 25S rRNA in the *ubi3 $\Delta$ ub-1* mutant (which contained the integrated, single-copy *ubi3 $\Delta$ ub* allele), RNA from this and control strains was electrophoresed on an agarose gel and visualized by ethidium staining (Fig. 6b). A deficiency of 18S rRNA was clearly visible in the *ubi3 $\Delta$ ub-1* mutant, although it was not as pronounced as in the *ubi3* mutant (Fig. 6b). A wild-type (1:1) stoichiometry of 18S rRNA to 25S rRNA was seen in the *ubi3 $\Delta$ ub-2* mutant, which contained multiple copies of *ubi3 $\Delta$ ub* (Fig. 6b). Thus, deletion of the ubiquitin-coding element of *UBI3* leads to a deficiency of 18S rRNA which can be suppressed by amplifying the copy number of the free tail-expressing allele of the *UBI3* gene. This indicates that the ubiquitin-coding portion of the *UBI3* gene, although not strictly required for the processing of

20S pre-rRNA, facilitates this processing reaction, apparently by increasing the efficiency of incorporation of the *UBI3* tail into the nascent 40S ribosomal subunit.

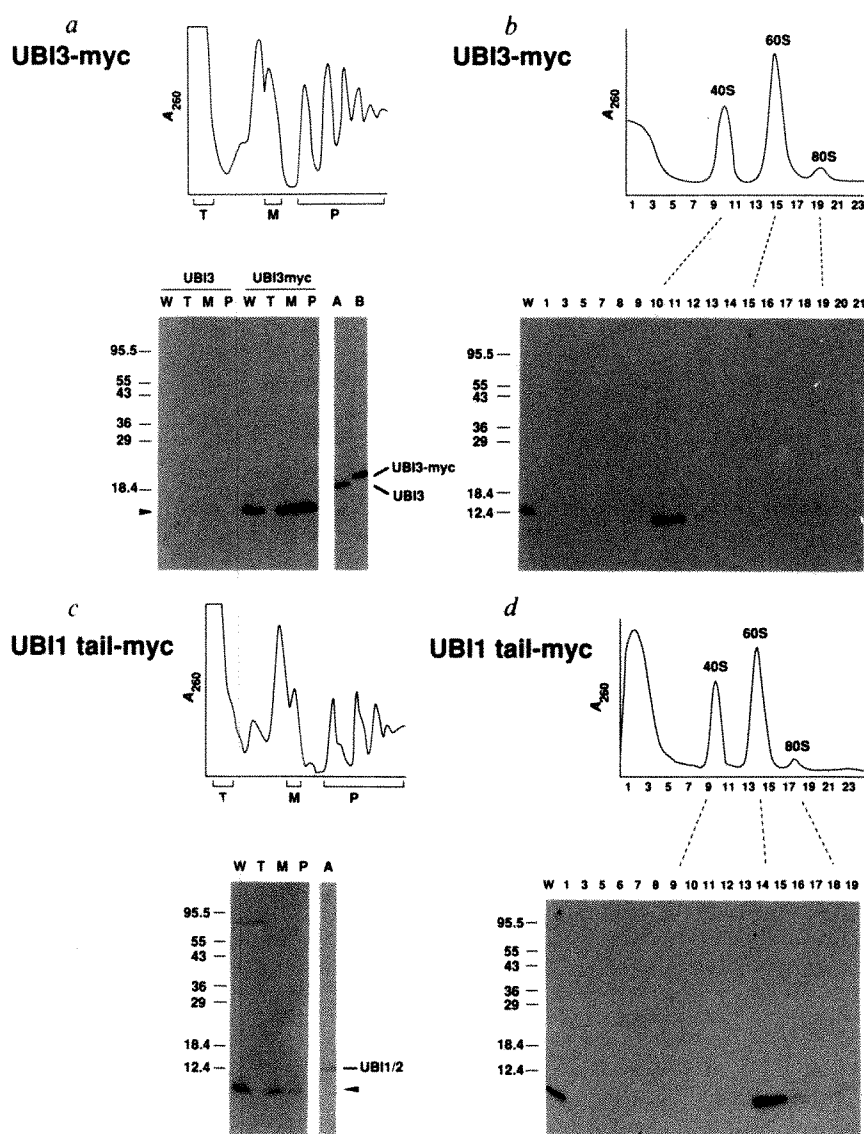

To test whether the effect of deleting the ubiquitin coding sequence of *UBI3* on tail function was achieved through a post-translational mechanism, *UBI3* mRNA levels were determined in *ubi3 $\Delta$ ub-1* and control strains. The northern hybridization analysis of Fig. 6c showed that the effect of the *ubi3 $\Delta$ ub-1* mutation on *UBI3* tail function is not achieved by decreasing the level of *UBI3* mRNA; instead, the *ubi3 $\Delta$ ub-1* mRNA is considerably more abundant than that of *UBI3*. Thus, the primary functional defect of the *ubi3 $\Delta$ ub-1* mutant lies in either a cotranslational or post-translational process. We conclude that the effective levels of newly synthesized *UBI3* tail protein, as reflected by its capacity to accelerate the processing of 20S pre-rRNA (Figs 3, 6), are significantly enhanced by its transient covalent association with ubiquitin.

## Discussion

Ubiquitin has previously been shown to function as a post-

FIG. 5 Immunoblot analysis of *S. cerevisiae* extracts fractionated in sucrose gradients to resolve either polyribosomes (a, c) or dissociated 40S and 60S subunits (b, d). In panels a and c, fractions were pooled as shown: W, whole-cell extract; T, top of gradient; M, monosomes; P, polyribosomes. a, Polyribosomal fractions from *ubi3* cells carrying either *UBI3* (lanes 1–4) or *UBI3-myc* (lanes 5–8) on a *CEN* plasmid, probed with anti-Myc antibody. Lanes A and B show the unprocessed (non-deubiquitinated) *UBI3* and *UBI3-myc* produced in *E. coli* and probed with anti-ubiquitin antibody<sup>21</sup>. b, Ribosomal subunit fractions from *ubi3* cells carrying *UBI3-myc* on a *CEN* plasmid, probed with anti-Myc antibody. c, Polyribosomal fractions from *ubi1 ubi2* cells carrying *UBI1 tail-myc* on a 2 $\mu$  plasmid, probed with anti-Myc antibody. Lane A shows unprocessed *UBI1* produced in *E. coli* and probed with anti-ubiquitin antibody. d, Ribosomal subunit fractions from *ubi1 ubi2* cells carrying *UBI1 tail-myc* on a 2 $\mu$  plasmid, probed with anti-Myc antibody. In c, the monosome and polyribosome peaks each have a shoulder of more rapidly sedimenting material. Similar results have been obtained with unrelated mutants deficient in large ribosomal subunits<sup>54</sup>, as is the *ubi1* strain (Fig. 4). The shoulder seems to represent mRNAs which have bound the 40S ribosomal subunit to form a preinitiation complex, but have not proceeded to bind a 60S subunit because the level of free 60S subunits is low<sup>54</sup>. Molecular weights are shown in thousands.

**METHODS.** To construct pUb54, the 1.3-kb *HincII* fragment from *UBI3* was ligated to the 0.7-kb *HincII*–*SphI* fragment of the plasmid AHSM (ref. 55) and inserted into YCp50 (ref. 50). The resulting plasmid encodes *UBI3-myc*, in which the last two amino acids of *UBI3* are replaced by the 12-residue Myc tag. To construct pUb62, the ~30-bp *Bam*HI–*Hind*III fragment of pUb92, encoding the first seven residues of the *UBI1* tail, was replaced by a synthetic oligonucleotide encoding the 12-residue Myc tag followed by the first seven residues of the *UBI1* tail. (A C-terminal fusion of Myc to *UBI2* did not complement the *ubi1 ubi2* double mutation; data not shown). The resulting plasmid was cut with *Eco*RI and *Eco*RV and the 2.3-kb fragment containing *UBI1 tail-myc* was cloned into the *Sma*I site of YEp351 (ref. 49), yielding pUb62. For the preparation of polyribosomes, cells were grown to an  $A_{600}$  ~0.5. Extracts were prepared<sup>31</sup> and analysed<sup>53</sup> as described. Gradients were centrifuged in an SW41 rotor at 15,000 r.p.m. for 16 h. Proteins were precipitated with 25% trichloroacetic acid, the pellets washed, dissolved and electrophoresed and electroblotted as in Fig. 1. Filters were probed with the Myc1-9E10 antibody<sup>35</sup> followed by <sup>125</sup>I-labelled sheep

anti-mouse IgG, using standard techniques<sup>8</sup>. Preparation of extracts for the analysis of ribosomal subunits was as in the Fig. 4 legend, except that extracts were brought to 0.5 M KCl before loading onto 15–35% sucrose gradients prepared as in the Fig. 4 legend but with the addition of 0.5 M KCl. Gradients were centrifuged in an SW41 rotor at 21,000 r.p.m. for 17 h at 10 °C.

translational modifying group which signals the degradation of acceptor proteins. Here, we describe a second mechanism of ubiquitin function in which ubiquitin is cotranslationally joined to an acceptor protein and serves to promote the assembly of the acceptor protein into a specific cellular structure. The role we have described for ubiquitin in the biogenesis of ribosomes in yeast probably applies to eukaryotes in general, as close homologues of the *UBI1-UBI3* genes exist in animals, plants

and lower eukaryotes<sup>7,25</sup>. Moreover, sequences homologous to the tail components of *UBI1-UBI3* have invariably been found fused to ubiquitin.

*UBI1-UBI3* form a subset of a class of genes in which an element encoding either ubiquitin or an amino-acid sequence similar to that of ubiquitin is fused to a downstream coding sequence. Although no systematic effort to identify such genes has yet been reported, four loci encoding C-terminally extended ubiquitin-like polypeptides have already been described. These are: first, the *An-1* gene, whose transcripts are segregated to the animal pole of *Xenopus laevis* embryos (D. Weeks and D. Melton, personal communication); second, a human gene that encodes an interferon-inducible protein with a relative molecular mass of about 15,000 (refs 38, 39); third, the constitutively expressed human gene *GdX* (ref. 40); and finally, the large open reading frame of the togavirus BVDV (bovine viral diarrhoea virus), which encodes a ubiquitin-like sequence embedded within the nonstructural viral polyprotein<sup>41</sup>. Because of their substantial divergence from the canonical, highly conserved ubiquitin sequence, the ubiquitin-like proteins cannot serve as precursors to ubiquitin, in contrast to the *UBI1-UBI3* proteins. Moreover, the processing proteases that remove ubiquitin from ubiquitin fusion proteins are expected to be virtually inactive upon the ubiquitin-like proteins, because the bond that would be cleaved is flanked by amino-acid substitutions that block (or are expected to block) cleavage of engineered ubiquitin fusion proteins<sup>36,42</sup>. We suggest that the function of ubiquitin-like protein domains may be to enhance the function of linked non-ubiquitin domains in a way similar to that seen in the *UBI3* protein.

It has recently been shown that certain proteins, known as 'molecular chaperones', associate transiently (and non-covalently) with newly synthesized polypeptide chains and so facilitate their incorporation into oligomeric structures<sup>43-45</sup>. By definition, molecular chaperones do not form part of the final oligomeric structure, nor do they necessarily possess steric information specifying the structure's assembly<sup>43</sup>. By these criteria, it seems that the ubiquitin moiety of the *UBI3* protein acts as a molecular chaperone of the *UBI3* tail in facilitating its incorporation into ribosomes. The covalent, cotranslational association of a chaperone protein with its ligand has several potential advantages: the N-terminal chaperone is bound to and can protect its ligand from the moment the ligand is synthesized; the chaperone can transiently block, or shelter, the N-terminus of its ligand (which may serve as a signal for degradation in some proteins<sup>36</sup>); and finally, the cotranslational chaperone can bind its ligand without needing a specific recognition site in the ligand.

It is probable that the ubiquitin tails, like other ribosomal proteins<sup>30</sup>, are extremely short-lived if they are not assembled within ribosomes. Thus, the transient attachment of ubiquitin to the N-termini of the *UBI1-UBI3* tails could increase the efficiency of their incorporation into nascent ribosomes by a transient metabolic stabilization of the newly formed tails. Although ubiquitination of a protein can signal its degradation, this activity seems to require multi-ubiquitin chains<sup>23</sup>. Rather than directly protecting the *UBI1-UBI3* tails against degradation, ubiquitination could increase the rate of the tails' transport to, or assembly within, nascent ribosomes, thus decreasing the proportion of newly synthesized tails that are degraded in transit to the ribosome. Experiments to distinguish between these possibilities are in progress. □

FIG. 6 Characterization of mutants bearing single or multiple copies of the *ubi3Δub* allele. *a*, Growth defect of the *ubi3Δub-1* mutant. Cultures were streaked onto YPD plates and incubated for 3 days at 30 °C. Quadrant designations are as follows: WT, wild-type; *ubi3Δub-1*, a growth revertant obtained through integrative transformation of a *ubi3* strain with a DNA fragment carrying the *ubi3Δub* deletion mutation (single-copy integration); *ubi3Δub-2*, as *ubi3Δub-1*, except that 3–4 copies of the transforming DNA fragment integrated tandemly at the *UBI3* locus; *ubi3*, which forms sizeable colonies only after 1 week. *b*, 18S rRNA deficiency in the *ubi3Δub-1* mutant. RNA was resolved on a 1% agarose gel in the presence of ethidium bromide, and photographed under UV light. Designations are as in *a*, except for lane WT (rev), which contained RNA from a phenotypically wild-type revertant obtained through integrative transformation of a *ubi3* strain with a DNA fragment carrying the wild-type *UBI3* gene. *c*, Northern hybridization analysis of *UBI3* RNA levels in mutant strains. Closed arrow, *UBI3* RNA; open arrow, *ubi3Δub* RNA.

**METHODS.** Growth revertants were selected on YPD plates at 23 °C, a temperature at which the (cold-sensitive) *ubi3* mutants form colonies only after more than two weeks. Transformants were screened for loss of the *ubi3*-linked *HIS3* marker before Southern hybridization analysis. *b* and *c*, RNA was prepared from cells grown in YPD, and electrophoresed as in Fig. 3, except that in *c* a 1.5% agarose gel was used, then transferred onto a Gene Screen filter (New England Nuclear), and UV-irradiated as described<sup>8</sup>. Hybridization was carried out at 37 °C in a solution containing 40% formamide, 7% SDS, and 5×SSPE. The filter was washed at 62 °C in 1% SDS, 1×SSPE. The *UBI3* hybridization probe was the insert from pUB36 (see the Fig. 2 legend). The probe was radiolabelled as described<sup>8</sup>. In *c*, 10 μg of RNA was loaded onto each lane; *b*, loads were slightly adjusted to equalize the intensities of the 25S rRNA bands to facilitate comparison of 25S rRNA:18S rRNA ratios between the lanes. To increase the sensitivity of detection, formaldehyde was omitted from the gel in *b*. In *c*, only one *UBI3* mRNA (of ~0.7 kb) was detectable in wild-type cells. This and other data, including an analysis of transcripts in the *ubi3* mutant (data not shown), indicate that the 1.8 kb and 1.0 kb mRNAs previously considered to be additional *UBI3* transcripts<sup>24</sup> are not in fact derived from the *UBI3* locus.

ACKNOWLEDGEMENTS. We thank Mary Jalenak for assistance in characterizing mutants, John McGrath for carrying out sequence searches, Joan Park and Andreas Bachmair for helpful discussions, Vincent Chau for the anti-ubiquitin antibody, Tauseef Butt and David Ecker for the plasmid YEp46, Sean Munro for advice on peptide tagging, Brian Seed for advice on RNA electrophoresis, members of this laboratory for comments on the manuscript, Daniel Weeks and Douglas Melton for permission to cite unpublished data, and Barbara Doran for secretarial assistance. This work was supported by grants to A.V. from the NIH. B.B. was supported by a predoctoral fellowship from the NSF.

## LETTERS TO NATURE

## An alternative binary model for SN1987A

Ph. Podsiadlowski & P. C. Joss

Department of Physics, Center for Space Research, and  
Center for Theoretical Physics, Massachusetts Institute of Technology,  
Room 6-203, Cambridge, Massachusetts 02139, USA

FABIAN *et al.*<sup>1</sup> and Joss *et al.*<sup>2</sup> have proposed that the progenitor of supernova 1987A was a relatively faint binary companion of the blue supergiant Sk-69°202 (ref. 3). Here we propose another class of models for SN1987A, wherein Sk-69°202 was the progenitor, but where the presupernova evolution of this star was strongly influenced by the accretion of matter from a companion star which was initially the more massive star. Binary stellar evolution calculations show that a model of this type can naturally explain why the apparent progenitor was a blue supergiant rather than a red one. The system becomes unbound after the supernova event, and the presence of a normal or neutron-star companion will probably be revealed a few years after the explosion. A model of this type can explain all the major observational features of SN1987A and also provides plausible explanations for many of its anomalies.

SN1987A has enriched many fields of astrophysics as well as some related disciplines. Surprisingly, however, the greatest challenge it has posed is to stellar evolution theory: why was the apparent progenitor (Sk-69°202; ref. 3) a blue supergiant rather than a red supergiant, the generally preferred precursor of type II supernovae<sup>4,5</sup>? Numerous single-star models for the progenitor have been advanced to explain this unexpected behaviour, but all of them face significant objections (for a review of single-star models see, for example, ref. 6 and references therein).

The resolution of this puzzle is of great importance. An understanding of the presupernova evolution would allow us to decide whether SN1987A was a unique event or was representative of a whole class of supernovae which are too faint to be easily detected outside the Local Group. Moreover, if this supernova is telling us something about the evolution of massive stars, it may turn out to be a Rosetta stone against which the theory of stellar evolution can be calibrated.

Most stars occur in binary or multiple systems<sup>7</sup>. If we allow that the supernova progenitor may have been a member of a binary, several alternative models present themselves. In one class of models, the star that exploded was not Sk-69°202, but a previously undetected companion star<sup>1,2</sup>. These models predict that Sk-69°202 will reappear when the photosphere of the supernova has receded sufficiently. In this letter we propose a different type of model, in which the progenitor was a blue rather than a red supergiant because of its past interaction with its companion. Our calculations also shed new light on the features that single-star models must have to account for the observed properties of SN1987A.

Whether a star ends its life as a red or a blue supergiant depends on some rather subtle aspects of the physics of the stellar envelope and is not entirely amenable to heuristic explanation. However, many of the essential features of the envelope physics can be described in terms of how much luminosity can be carried in the envelope by radiative diffusion (refs 8, 9; but see also refs 10 and 11). If the luminosity of a star during the course of its evolution reaches a critical value,  $L_{\text{crit}}$ , a thermal instability triggers a runaway expansion of the envelope (ref. 8) and drives the star redward toward the Hayashi track.  $L_{\text{crit}}$  is a sensitive function of the radiative opacities in the envelope and increases with decreasing opacities, a result that accounts for the requirement of very low metallicities in most single-star models for SN1987A.  $L_{\text{crit}}$  is also very sensitive to the fractional core mass  $q_c \equiv M_c/M$ , where  $M_c$  is the mass of the hydrogen-exhausted core and  $M$  is the total mass of the star. It is well known from the theory of the evolution of massive stars that a reduction in envelope mass (for example, by mass loss through a stellar wind) and a consequent increase in  $q_c$  reduces  $L_{\text{crit}}$  and favours redward motion in the Hertzsprung-Russell diagram<sup>12</sup>. Conversely, a decrease in  $q_c$  (for example, by accretion of matter from a close-binary companion) increases  $L_{\text{crit}}$ , and the transition to the red-supergiant stage may thereby be prevented (or reversed if it has already occurred).

To determine whether this mechanism may explain the seemingly anomalous colour of Sk-69°202, we have performed a series of stellar evolution calculations in which such accretion is allowed to occur. We used a standard Henyey-type code<sup>13</sup>, and we assumed an initial metallicity of  $Z = 0.02$  and that convection was governed by the Schwarzschild instability

criterion, with a convective mixing length equal to 1.5 pressure scale heights, and with the effects of convective overshooting and semiconvection included according to the prescription given by Iben<sup>14</sup>. We followed the evolution of three stellar models with initial masses of 15, 17 and 20  $M_{\odot}$  from the zero-age main sequence to the onset of core carbon burning. After the termination of the core hydrogen-burning phase, we accreted 5  $M_{\odot}$  onto the 15- $M_{\odot}$  model and 3  $M_{\odot}$  onto the 17- $M_{\odot}$  model. Thus, all three models had a final mass of 20  $M_{\odot}$ ; the masses of the hydrogen-exhausted cores were 4.5, 5.3 and 6.4  $M_{\odot}$  respectively. We assume that the time that has elapsed since the end of the mass-transfer episode is long compared with the Kelvin time,  $\tau_K \approx 10^4$  yr, of the progenitor, so that the appearance of the progenitor just before the supernova event should be essentially independent of the details of mass transfer.

The results of our calculations are illustrated in Fig. 1. Models with final values of  $q_c$  larger than a certain critical value  $q_c^0$  are red supergiants (on the Hayashi track in the H-R diagram) just before becoming supernovae, whereas models with  $q_c < q_c^0$  end their lives as blue supergiants. (For our chosen values of  $Z$  and final stellar mass, we find that  $q_c^0 \approx 0.28$ , but this value is sensitive to the parameters of the model.) The effective temperature of the star just before the supernova event increases monotonically (that is, the pre-supernova is increasingly blue) with increasing accreted mass.

Some of our detailed numerical results are sensitive to the assumed parameters of our models, but our qualitative con-

clusions regarding the viability of our binary models for SN1987A are insensitive to the assumed metallicity, the treatment of convection, the details of the mass-transfer process, and the amount of mass that may be lost by the supernova progenitor in a stellar wind following the mass-transfer phase. For our basic model to work, we require only that at least several solar masses more be accreted by the progenitor than are subsequently lost as a stellar wind. We also find that the dependence of the stellar luminosity on the core mass of the progenitor is much weaker than predicted by the core mass-luminosity relation for single massive stars in this evolutionary phase (see for example refs 15 and 16). We thus conclude that the luminosity does not accurately determine the core mass of a star that has accreted a substantial amount of matter after the termination of core hydrogen burning.

For the requisite binary evolution to occur, the supernova progenitor must have been originally the less massive star of a close binary system, because the original primary fills its critical lobe first and becomes the mass donor. From our evolutionary calculations, we also find that if mass transfer occurs before the supernova progenitor has completed core hydrogen burning, the progenitor will be rejuvenated as a main-sequence star and will subsequently mimic the standard evolution of a more massive single star; evolutionary scenarios are therefore also constrained by the requirement that the progenitor must complete core hydrogen burning before mass transfer begins. There are then two possible scenarios, involving case B (ref. 17) and case C (ref. 18) mass transfer, respectively, which have very different consequences.

In case B, the primary fills its critical lobe when it is on the first red-giant branch. As the supernova progenitor must have already left the main sequence before mass transfer begins, and as the main-sequence lifetime of a massive star is long compared with the interval from the termination of core hydrogen burning to the tip of the red-giant branch, then the original mass of the supernova progenitor must be very close to that of the primary. Using the results for our 15- $M_{\odot}$  model, we find that the original mass of the supernova progenitor must be within  $\sim 0.3\%$  of the original mass of the primary. Binary systems composed of stars with the requisite masses and initial orbital separations (of the order of a few AU) will be rather rare, although a large fraction of all close binaries do in fact contain stars of approximately equal mass<sup>7,19</sup>.

Because of the mass increase, the post-main-sequence evolution of the supernova progenitor is faster than the corresponding evolution of the original primary, and the progenitor will reach the supernova stage earlier than the primary (by as much as  $\sim 10^5$  yr for our 15- $M_{\odot}$  model). In this case, Sk - 69°202 would have had a stellar companion before the supernova event. However, as more than half the mass of the binary system should have been ejected in the supernova explosion, the system should not have remained bound, and the erstwhile companion should be revealed when or shortly after it crosses the photosphere of the supernova (unless the motion happens to be nearly directly away from the Earth). We estimate that this should occur about 1-3 yr after the explosion.

The constraint on the relative masses of the binary components for case C mass transfer is much weaker than in case B: the supernova progenitor must still be originally the less massive of the two, but its mass may differ from that of the original primary by as much as  $\sim 10\%$ . In this case, mass transfer occurs when the original primary reaches the asymptotic giant branch (after the completion of helium core-burning), whereas the supernova progenitor can be in any preceding post-main-sequence phase. The original primary then explodes as a supernova shortly after the mass-transfer phase and should leave a neutron-star remnant (this explosion occurred in the rather distant past and should not be confused with the observed supernova event). The binary system remains bound but acquires a small eccentricity,  $e \approx 0.1-0.2$ . For up to some  $10^6$  yr after-

FIG. 1 Evolutionary tracks of the progenitor in the Hertzsprung-Russell diagram (stellar luminosity,  $L$ , versus effective temperature,  $T_{\text{eff}}$ ) for several assumed amounts of accreted mass. *a*, Evolutionary track of a 20- $M_{\odot}$  star without accretion. *b*, Evolutionary track of a star with an initial mass of 17  $M_{\odot}$  which accretes 3  $M_{\odot}$  after the termination of core hydrogen burning (the dotted portion of the curve denotes the mass-transfer phase; the arrow indicates the onset of mass transfer). *c*, Evolutionary track for a star with an initial mass of 15  $M_{\odot}$  which accretes 5  $M_{\odot}$  after the core hydrogen-burning phase; here, the small break in the curve denotes the mass-transfer phase. In each case,  $M_{\text{in}}$  denotes the initial mass and  $q_c \equiv M_c/M$  is the final fractional core mass,  $M_c$  being the mass of the hydrogen-exhausted core and  $M = 20 M_{\odot}$ , the final mass of the progenitor. The asterisks indicate the parameters of the models just before the supernova event. For comparison, the final parameters of all three cases are shown in each panel.

wards, while the supernova progenitor undergoes advanced evolutionary phases, the neutron star will accrete a portion of any stellar wind emitted by the progenitor. Using the Bondi-Hoyle model<sup>20</sup> for wind accretion, we find that the expected X-ray luminosity,  $L_X \approx 1 \times 10^{34}$  ergs s<sup>-1</sup>, is well below the upper limit for the X-ray luminosity in the direction of SN1987A obtained from archival Einstein data<sup>21</sup> ( $L_X \leq 9 \times 10^{34}$  ergs s<sup>-1</sup>).

More than half the total mass of the binary system will have been ejected in the observed supernova explosion, and the system will now be unbound. The older neutron star (the collapsed remnant of the original primary) may become detectable within the next few years, either as a radio pulsar or as an X-ray source powered by the accretion of material from the supernova remnant.

The principal advantage of either of the above scenarios over single-star models for SN1987A is that a blue progenitor is a natural consequence of conventional binary stellar evolution theory, and does not depend on *ad hoc* assumptions or modifications of the input physics. Moreover, our binary model may account for many of the anomalous features of SN1987A (see also ref. 2). In particular, the natural structure of our pre-supernova model is sufficiently similar to those of single-star models<sup>15,22,23</sup> that we can expect fits to the supernova light curve entirely as good as those achieved in the single-star models. The asymmetric expansion of the ejecta, as inferred from polarization measurements and speckle interferometry<sup>24,25</sup>, also has a natural explanation in our model, as we expect the progenitor to be rotationally flattened as a result of the spin-up it experienced during the mass accretion phase (see also R. A. Chevalier, preprint). Moreover, the relativistic-jet models<sup>26</sup> that have been invoked to explain the 'mystery spot'<sup>27</sup> seem to require a close-binary companion, and the existence of a nearby companion star may account for the observed variability<sup>28</sup> of the soft X-ray emission (ref. 29 and R. McCray, personal communication).

Our model also provides a plausible mechanism to explain the anomalously high abundance of barium and other s-process elements in the ejecta<sup>30</sup>. If the companion passed through a helium-giant phase<sup>31</sup>, s-processed material might have been dredged up<sup>32</sup> and subsequently transferred to the progenitor by Roche-lobe overflow. Alternatively, mass transfer might spin up the progenitor nearly to break-up velocity, in which case meridional currents might overcome the stabilizing effect of chemical gradients<sup>33</sup> and produce large-scale mixing of the envelope, including the dredge-up of s-processed material (see also refs 34 and 35). We note that there is no known mechanism to account for this anomaly in single-star scenarios for SN1987A and that all known barium stars are found in binary systems<sup>36</sup>.

Future observations of the supernova and its environment (such as the nitrogen-rich circumstellar material<sup>37</sup>) will help to distinguish between the single star and the binary models. However, the ultimate test will be the reappearance of the predicted companion star, be it a relatively normal star, a neutron star, or Sk-69°202 itself. We should know within a few years whether SN1987A was a member of a binary system and, if so, which of the proposed binary models is correct. □

ACKNOWLEDGEMENTS. This work was supported in part by the National Aeronautics and Space Administration. We are grateful to L. Nelson for providing us with a copy of his stellar evolution code and for many helpful discussions concerning the modification and implementation of the code, and we thank D. VandenBerg for supplying us with his opacity tables.

## Stabilization of lamellar oil-water liquid crystals by surfactant/co-surfactant monolayers

L. F. Braganza\*, M. Dubois† & J. Tabony††

LIQUID crystals are divided into two main classes, thermotropic and lyotropic. Thermotropic liquid crystals are formed by melting, whereas lyotropic liquid crystals arise from the association of molecules, such as soap and water, that in general are not in themselves liquid crystalline. Thermotropic liquid crystals are used for liquid-crystal displays; lyotropic liquid crystals occur in living cells. Here we report a novel sequence of lyotropic liquid crystals comprising alternate layers of oil and water whose thickness varies linearly with the relative proportions of oil and water, and we have determined their structure using neutron diffraction methods. The oil and water layers are separated and stabilized by a monolayer film of surfactant and co-surfactant. The individual layers are typically a hundred ångströms or more in thickness, and total lamellar spacings of up to 1,000 Å were observed. This behaviour is difficult to describe in terms of the theories of colloid stability currently used to describe lyotropic liquid crystals. An understanding of the self-organization of such systems over such large distances would elucidate how long-range liquid-crystalline ordering arises in living cells. Moreover, thermotropic liquid crystals are expensive and chemically relatively unstable, and lamellar mesophases of the lyotropic type described here could lead to inexpensive, chemically stable liquid-crystalline materials suitable for industrial application.

Lamellar mesophases of surfactant/water liquid crystals<sup>1</sup> are well characterized structures comprising alternate surfactant bilayer sheets and water layers about 30 Å thick. Diluting these mesophases rarely results in lamellar repeat spacing of more than 100 Å; instead, either a micellar phase is formed or phase separation occurs. Dispersions of oil and water stabilized by surfactant and co-surfactant frequently form fluid isotropic microemulsions<sup>2</sup>. Under some circumstances, however, such

† Present address: Département de Recherche Fondamentale, CEN Grenoble, 85X Grenoble Cedex, France.

mixtures can give rise to liquid-crystalline phases that have lamellar, hexagonal or cubic structures<sup>3-5</sup>. We have studied the lamellar mesophases prepared from tetradecyltrimethylammonium bromide (TTAB,  $C_{14}H_{29}N^+(CH_3)_3Br^-$ ) as surfactant, pentanol as co-surfactant, cyclohexane and water. Three series of compositions were studied: in series A and B, the amounts of surfactant and co-surfactant were constant, as was the total volume of cyclohexane and water, but the relative volume fraction of cyclohexane to water was varied. In series C, the lamellar phase was gradually diluted with an aqueous solution of 1% by weight of sodium bromide pre-saturated with pentanol and cyclohexane. The compositions were as follows: (A) 0.70 g TTAB, 0.38 ml pentanol, 4.0 ml of water and cyclohexane; (B) 0.29 g TTAB, 0.33 ml pentanol, 4.2 ml of water and cyclohexane; (C) TTAB/pentanol/cyclohexane in the weight ratio 1:0.56:0.55 in a 1% by weight solution of NaBr pre-saturated with cyclohexane and pentanol. For composition C the overall TTAB concentration varied from that used in composition B down to one eighth of this value.

In the absence of cyclohexane, composition A formed a birefringent phase which persisted on replacement of water by oil for oil-to-water volume fractions of 90% cyclohexane/10% water. Composition B was not liquid crystalline in the absence of oil but formed a birefringent phase as soon as a small amount of cyclohexane was added. The birefringent phase was stable for samples containing up to 70% cyclohexane/30% water, after which phase separation occurred into optically birefringent and isotropic phases. For surfactant concentrations much less than those used in series B, the oil-in-water lamellar phases became unstable. Stable lamellar phases down to much lower concentrations were obtained by using an aqueous solution of NaBr instead of water.

All the birefringent phases gave neutron diffraction patterns consistent with a lamellar structure, and up to three diffraction orders were observed. For compositions A and B, the overall repeat spacings were 130 Å and 230 Å respectively. The lamellar mesophases orientate in magnetic fields; Fig. 1 shows the neutron intensity distribution over a two-dimensional detector from a typical orientated sample. Neutron-scattering-length densities of protonated and deuterated materials are of very different magnitude. Hence, in multicomponent systems, selective deuteration of different components can be used to highlight

FIG. 1 Neutron scattering pattern on a two-dimensional  $64 \times 64$  cm detector for an orientated mesophase with an oil-to-water volume fraction of 45% cyclohexane/55%  $D_2O$ . The sample composition was 0.70 g tetradecyltrimethylammonium bromide, 0.38 ml pentanol, 1.80 ml cyclohexane and 2.20 ml  $D_2O$ . All measurements were done on the D17 diffractometer<sup>17</sup> at the Institut Laue-Langevin, Grenoble, France. The pattern was recorded in 20 min using a sample-to-detector distance of 1.40 m and a wavelength of 9.0 Å. The neutron beam, stopped by a rectangular cadmium plate after transmission through the sample, is centred on the detector; two reflections on either side correspond to the first and second lamellar diffraction orders. Orientation was achieved by cooling the sample from 60 °C to 20 °C in a magnetic field of 6.5 tesla over 4 h. Shown in the figure is the direction of the magnetic field,  $H$ , with respect to the detector.

specific features of the structure. Figure 2 shows a Fourier profile, derived from the phased structure factors using standard procedures<sup>6</sup>, for a mesophase of composition A. The profile corresponds to a low-resolution image of the variation in neutron-scattering-length density normal to the lamellae. Both the water and cyclohexane were deuterated; the maxima correspond to the layers of deuterated oil and water, and minima correspond to the protonated surfactant/co-surfactant layers. Fourier profiles obtained for samples containing either surfactant or pentanol as the only protonated components were nearly identical to those in Fig. 2, indicating that these two components share a common location within the structure. Most of the pentanol molecules are therefore intercalated between the surfactant chains. Deuteration of oil or water reduces alternate maxima, corresponding to either the protonated oil or water layers, to the level of the protonated surfactant/co-surfactant minima. For samples consisting of  $D_2O$ , deuterated cyclohexane, deuterated pentanol and  $C_{14}D_{29}N(CH_3)_3Br^-$ , the scattering arises solely from the surfactant polar heads. The thickness of the surfactant/co-surfactant layer was determined as  $\sim 17$  Å, equal to half of the bilayer thickness derived from samples containing no cyclohexane. These results show that the lamellar structure comprises alternating layers of cyclohexane and water separated and stabilized by a monolayer film of surfactant and co-surfactant. As the cyclohexane-to-water volume fraction increases, there is no change in the total repeat spacing but the cyclohexane layer thickens at the expense of the water region. Shown in Fig. 3 are plots of the overall spacing and the thicknesses of cyclohexane and water layers versus the cyclohexane-to-water volume fraction. The cyclohexane layer thickness increases almost linearly with oil content, and a corresponding decrease occurs in the  $D_2O$  layers, until for composition A at 90% cyclohexane/10%  $D_2O$  the  $D_2O$  layer thickness is  $\sim 10$  Å. Similar results were obtained for composition B, for which the overall repeat-unit thickness was 230 Å, and the cyclohexane and  $D_2O$  layer thicknesses, just before phase separation (at an oil-to-water volume fraction of greater than 70% cyclohexane/30%  $D_2O$ ), were  $\sim 110$  Å and  $\sim 80$  Å, respectively. For

FIG. 2 Scattering-length density profile at  $20.0 \pm 0.2$  °C for a mesophase composed of 0.70 g tetradecyltrimethylammonium bromide, 0.38 ml pentanol, 1.4 ml deuterated cyclohexane and 2.6 ml  $D_2O$ . The repeat spacing is  $125 \pm 2$  Å. Also shown is a schematic drawing of the structure, with pentanol molecules represented as dark rods intercalated between surfactant molecules. The Fourier profiles were calculated from  $\rho(x) = \pm |F_n| \cos(2\pi nx/d)$ , where  $\rho(x)$  is the coherent scattering amplitude density,  $|F_n|$  is the structure-factor modulus of the  $n$ th order diffraction peak and  $d$  is the repeat spacing. Because preparations with different oil-to-water volume ratios gave different degrees of magnetic orientation, non-orientated samples were used, and structure factors were calculated from the diffraction intensities  $I_n$  according to  $|F_n| = (\sin 2\theta_n \sin \theta_n)^{1/2} I_n^{1/2}$ , where  $(\sin 2\theta_n \sin \theta_n)$  is the Lorentz factor as applied to randomly orientated or powder samples. Phases—equal to either zero or  $\pi$  for lamellar structures—were determined by substituting deuterated for protonated molecular components and by swelling the structure (by changing the temperature). Diffraction patterns were recorded typically in 60 min on the diffractometer D16 at the Institut Laue-Langevin<sup>11</sup>. Statistical errors in the structure factors were better than  $\pm 1\%$  for the strong reflections and a few per cent for the weak peaks.

composition C (1% NaBr solution), samples containing much less surfactant and co-surfactant were strongly birefringent, and the observed lamellar spacings ranged up to 1,000 Å.

In most surfactant-water mixtures, lamellar phases do not arise until concentrations of ~50% by weight are attained, such that the thicknesses of the surfactant bilayer and the water layer are comparable (~30 Å). The addition of a co-surfactant such as pentanol promotes the formation of lamellar phases at lower surfactant concentrations, giving higher spacings. For example, in the absence of cyclohexane, composition A forms a lamellar phase which persists down to surfactant concentrations of ~10% by weight. At lower concentrations, micelles are formed. This behaviour can be explained in the following manner. The pentanol molecules are intercalated between the surfactant hydrocarbon chains, reducing the curvature of the micelle-water interface until flat surfaces are formed and a lamellar packing results. The addition of both co-surfactant and oil favours the formation of a lamellar phase for surfactant concentrations even lower than 10% by weight; by adding KBr, lamellar phases formed at less than 1% of surfactant. Once a flat monolayer has been formed, the lamellar structure may be retained whilst significantly modifying the relative proportions of oil and water. There has been considerable debate concerning the structure of microemulsions containing equal volumes of oil and water<sup>7-9</sup>. One possibility comprises bicontinuous structures of cubic symmetry in which the local surface curvature is non-zero but the total curvature is very low<sup>3,7-9</sup>. Another possibility is the lamellar structures such as those reported here. It should be possible to effect a transition between the two types of structure by varying the co-surfactant content and thus modifying the local interfacial curvature.

These arguments based on interfacial curvature may help to explain why these lamellar structures arise. However, the nature of the forces operative in this system, for which aqueous-based or oil-rich mesophases can be prepared with neither loss of the lamellar structure nor a change in the repeat structure, remains to be determined. The stability of lamellar mesophases relative to other structures may be understood classically in terms of repulsive electrostatic interactions and attractive van der Waals forces<sup>10,11</sup>. Both of these contributions are strongly modified by replacing water by oil and both decay rapidly with increasing distance. Electrostatic interactions decay exponentially with the inverse Debye length. The Debye lengths calculated for the systems with no added NaBr varied from ~5 to 10 Å, and were less than 10 Å for the systems with added NaBr. Classical theories of electrostatics do not seem to account for the observed

behaviour; in particular, decreasing the Debye length by adding salt results in a stabilization of the lamellar phase to longer layer spacings. This, and the existence of a lamellar structure over a wide range of oil-to-water volume ratios, suggests that additional long-range forces might be operating. An interfacial-fluctuation-driven mechanism<sup>12</sup> has been suggested in this respect, but the applicability of this mechanism has not been established, and it is difficult to see how it can explain recent results obtained on clay/water systems<sup>13</sup>. For aqueous layers between hydrophobic surfaces, Israelachvili and Pashley *et al.*<sup>14,15</sup> deduced the presence of strong long-range attractive hydrophobic forces, which are difficult to explain in classical terms. If such long-range forces exist, then they would be of considerable importance in many areas of molecular biology and colloid science. The lamellar mesophases presented here may be suitable systems in which to probe their nature, by, for example, force-distance measurements. These lamellar oil-water mesophases may find several applications<sup>16</sup>. In particular, lyotropic liquid crystals with a range of tailored properties may be prepared by the inclusion of appropriate compounds or colloidal materials into the aqueous, hydrocarbon or interfacial regions. Structural studies of the type reported here are an essential step towards the development and exploitation of this novel technology. □

## Atmospheric <sup>14</sup>C and century-scale solar oscillations

Minze Stuiver & Thomas F. Braziunas

Department of Geological Sciences and Quaternary Research Center, University of Washington, Seattle, Washington 98195, USA

THE solar-wind plasma in our interplanetary space deflects part of the Earth-bound cosmic-ray flux through its magnetic interaction with the electrically charged incoming particles. Because changes in the magnetic properties of the plasma originate at the Sun's surface, the cosmic-ray flux arriving at Earth therefore depends on the changing surface conditions of the Sun. Consequently, by monitoring the variable production rate of cosmogenic isotopes (such as <sup>14</sup>C) in our atmosphere, a time history of changing conditions of the Sun's surface can be obtained. Trees, through carbon dioxide assimilation, lay down a <sup>14</sup>C record which provides clues towards the causes underlying <sup>14</sup>C production-rate changes. Here we show from maximum-entropy spectral analysis of a 9,600-yr high-precision <sup>14</sup>C chronology that changes occur in the Sun's convective zone with a fundamental oscillatory mode of about  $2.4 \times 10^{-3} \text{ yr}^{-1}$  (420-yr period), and we also identify several harmonics. Previous searches<sup>1-3</sup> for cyclicity in the atmospheric <sup>14</sup>C record have yielded periods near 140 and 200 yr. We discuss the implications of a longer and more precise <sup>14</sup>C record.

Determinations for this study were made by the precise counting of the  $^{14}\text{C}$  radioactivity of large samples, the sample activity being compared with the absolute National Bureau of Standards (NBS) oxalic acid standard activity. For tree-ring materials of known age a correction for  $^{14}\text{C}$  decay is applied. The  $^{14}\text{C}$  results are also normalized on a fixed  $\delta^{13}\text{C}$  value of  $-25\%$  relative to the PDB standard

$$\left(\delta^{13}\text{C} = \left[ \frac{(^{13}\text{C}/^{12}\text{C})_{\text{sample}}}{(^{13}\text{C}/^{12}\text{C})_{\text{PDB}}} - 1 \right] 1,000\% \right)$$

The results are expressed as  $\Delta^{14}\text{C}$  (ref. 4), which represents the  $^{13}\text{C}$ -normalized  $^{14}\text{C}$  activity at the time of formation, expressed as the deviation in parts per thousand from the oxalic acid standard activity.

A compilation of the tree-ring  $^{14}\text{C}$  data reported in ref. 5 yielded the basic 9,600-yr bi-decadal  $\Delta^{14}\text{C}$  record used here. The data of the Seattle<sup>6,7</sup> and Belfast<sup>7,8</sup> laboratories extend back to 5,200 yr BC, whereas a mixture of results from Seattle<sup>9</sup>, La Jolla<sup>10</sup>, Tucson<sup>11</sup> and Heidelberg<sup>12</sup> was used for the interval 5200–7750 BC. The Seattle–Belfast portions of the data set have a typical standard deviation of 1.5–2% for bi-decadal wood. Such precision includes overall reproducibility as well as the Poisson error in the number of counts. For pre-5200 BC data, the average standard deviation derived from the scatter of the results reported within 20-yr blocks is 5%.

The long-term  $\Delta^{14}\text{C}$  record shows a broad 10% decline towards the present, which is usually attributed to the influence either of an increasing geomagnetic dipole moment on  $^{14}\text{C}$  production rate or of changing carbon-reservoir parameters (that is, climatic conditions) on atmospheric  $^{14}\text{C}$ . Because we focus attention here on solar modulation of the cosmic-ray flux, the long-term trend was removed by subtracting a spline approximating a 400-yr moving average. Our contention that most, if not all, of the century-scale oscillations in the residual  $\Delta^{14}\text{C}$  record (Fig. 1) are heliomagnetic in origin is supported by calculations of the magnitude of the expected solar-induced  $\Delta^{14}\text{C}$  variations<sup>13</sup>, by the coincidence of the  $\Delta^{14}\text{C}$  maximum near AD 1700 with the lack of sunspots experienced during the AD 1654–1714 Maunder minimum<sup>13,14</sup>, by the compatibility of the  $^{14}\text{C}$  history of the last millennium with auroral evidence and naked-eye sunspot observations<sup>13,15</sup> and by the similarity (in timing as well as magnitude) of the  $^{10}\text{Be}$  cosmogenic record in ice cores and the atmospheric  $\Delta^{14}\text{C}$  record<sup>16</sup>.

The  $\Delta^{14}\text{C}$  oscillations of a few per cent in Fig. 1 have approximately equal rates of  $\Delta^{14}\text{C}$  increase and decrease. They differ slightly in length: the Maunder oscillations have a period of  $\sim 180$  yr and the Spörer oscillations last  $\sim 40$  yr longer<sup>17</sup>. These oscillations are denoted M and S in Fig. 1. Nine of the Maunder-type oscillations and eight of the Spörer variety are found in the 9,600-yr record. Episodes of triple oscillations, discussed later, are labelled  $T_1$ ,  $T_2$ ,  $T_3$  and  $T_4$ .

The atmospheric  $^{14}\text{C}$  signal results from frequency-dependent attenuation of variations in  $^{14}\text{C}$  production rate,  $Q$ , and so is a less direct record of heliomagnetic change than is  $Q$  itself. We calculated  $Q$  from the observed  $\Delta^{14}\text{C}$  record by carbon-reservoir modelling<sup>13,17</sup>, and determined the spectral distribution of the entire 9,600-yr  $Q$  record, without removing any trends. From a Fourier analysis, spectral power exceeding the  $2\sigma$  significance level<sup>18</sup> was found at periods of 230–200, 150, 88 and 57 yr. The maximum entropy method (MEM or autoregressive (AR) model), using the Burg<sup>19</sup> or FABNE<sup>20</sup> algorithms and AR order 20, yields spectral power for similar periods (Fig. 2). The minimum final-prediction error (FPE) was the selection criterion for AR order 20 (ref. 21). Virtually the same set of cycles (425, 227, 148, 85, 67, 58 and 45 yr) is found through the MEM approach (AR order 20) after de-trending  $Q$  in the same manner as shown in Fig. 1 for the atmospheric  $\Delta^{14}\text{C}$  record.

A set of harmonics underlies the periods in Fig. 2, as demonstrated by the inset, in which the hyperbola represents the

harmonics of the 420-yr period. The fourth harmonic, with a calculated period of 105 yr, is not present in the entire spectrum of Fig. 2, but on subdividing the record into four equal parts we find 110- and 107-yr cycles in, respectively, the 5350 BC–2970 BC and 570 BC–AD 1830 portions.

The cycles with 67-, 52- and 45-yr periods contain about one twentieth of the spectral power of the longer cycles in the Fourier spectrum. They may be related to the non-sinusoidal shape of the slower cycles. For instance, a square wave with a 420-yr period generates harmonics in our fast-Fourier-transform spectrum at about one twentieth of the strength of the 420-yr peak at periods of 139, 84, 60 and 47 yr.

The harmonics shown in Fig. 2 express the average oscillatory properties of the 9,600-yr record. A least-squares procedure was used to determine phase relationships and relative amplitudes for each of the principal oscillations (420, 218, 143 yr) generated by the MEM method. The iterative procedure involved testing combinations of phases and amplitudes for periods near each of the principal oscillation periods until a best fit with the observed record was achieved. The relative phases of the solar

FIG. 1 Residual atmospheric  $\Delta^{14}\text{C}$ , obtained by deducting the long-term  $\Delta^{14}\text{C}$  trend. M and S denote Maunder- and Spörer-type events. Episodes of triple oscillations ( $T_1$ – $T_4$ ) are discussed in the text.

FIG. 2 MEM power spectrum (AR=20) of  $^{14}\text{C}$  production rate  $Q$ . The periods are listed with the individual peaks. The hyperbola in the inset shows the harmonics expected for a fundamental frequency of  $1/420 \text{ yr}^{-1}$ . The observed periods are plotted in the inset with vertical bars representing one standard deviation (error bars smaller than the symbol size are not shown).

periodicities were assumed to remain unchanged for the entire 9,600-yr record. The periods obtained in this manner differ slightly from those in the raw MEM analysis.

Improved coherence is obtained for different sections of the record when two variants of the average (420, 218, 143 yr) mode are considered. Sections of the record ( $T_1$ ,  $T_2$ ,  $T_3$  and  $T_4$  in Fig. 1), each of which contains at least two of the Maunder- and Spörer-type digressions, show clear similarities when viewed on an amplified timescale<sup>17</sup>. A best fit to these segments, retaining their relative timing, yields equation (1), whereas the remaining sections are best represented by equation (2):

$$\frac{\Delta Q}{Q_t}(\%) = 8.8 \cos\left(\frac{2\pi}{435}t + 1.5\pi\right) + 11.2 \cos\left(\frac{2\pi}{207}t + 1.6\pi\right) + 5.6 \cos\left(\frac{2\pi}{148}t + 0.5\pi\right) \quad (1)$$

$$\frac{\Delta Q}{Q_t}(\%) = 2.8 \cos\left(\frac{2\pi}{456}t + \pi\right) + 4.3 \cos\left(\frac{2\pi}{256}t + 0.8\pi\right) + 3.4 \cos\left(\frac{2\pi}{143}t + 0.3\pi\right) \quad (2)$$

with  $\Delta Q/Q_t$  being the percentage deviation of  $Q$  from the splined long-term trend  $Q_t$ , and  $t$  being time in calendar years (negative for dates BC).

In Fig. 3b the solid curve shows the correlation coefficients between sliding 700-yr portions of equation (1) (435, 207, 148 variant) and the  $^{14}\text{C}$  production record, and the dotted curve gives the corresponding correlation for equation (2) (456, 256, 143 variant). The first variant generates the basic pattern of the four triplets  $T_1$ – $T_4$  without changing phase or amplitude of the sine waves (Fig. 3a).

The discussion so far has centred on the periodicities generated by the MEM method using moderate AR numbers. By increasing the AR order or using Fourier power spectra, additional periods become important. For instance, the single 420-yr peak (Fig. 2) splits into 504-, 355- and 299-yr peaks in the Fourier analysis of the complete de-trended  $Q$  record. Spectral properties also vary to some extent for different parts of the record (for example, in the 570 BC–AD 1830 quarter section a pronounced 127-yr peak, absent in the other sections, is observed).

FIG. 3 a, Tree-ring-derived changes in  $^{14}\text{C}$  production rate  $Q$  of the triplet episodes  $T_1$ – $T_4$  (solid line), compared with the curve generated from equation (1) (dotted line). Triplet intervals are 6480–5800 BC, 3420–2740 BC, 880–200 BC and AD 920–1600. b, Correlation coefficient  $r$  of a 700-yr sliding portion of the  $^{14}\text{C}$  production rate with curves generated from either equation (1) (solid line) or equation (2) (dotted line). The 700-yr sliding window results in a loss of 350 yr at either end of the curves.

Adding frequencies to equation (1) and using variable amplitude or phase shift would improve the correlation, but our goal here was to explain the major features of the  $^{14}\text{C}$  record in the least complicated manner.

Although we have argued that the main century-scale atmospheric  $^{14}\text{C}$  oscillations are best explained in terms of variations in  $^{14}\text{C}$  production rate induced by solar change, we have also considered the oceanic changes that would be required to produce these atmospheric patterns. Atmospheric  $\Delta^{14}\text{C}$  can increase either by a reduction in the  $\text{CO}_2$  gas exchange rate at the air-sea interface or by a reduction in the rate of upwelling of  $^{14}\text{C}$ -deficient deep ocean water. Carbon-reservoir modelling indicates that global wind speeds would have to be reduced to two-thirds of the current average to create a Maunder  $\Delta^{14}\text{C}$  event; alternatively, mixing rates in the global ocean would have to fall back rapidly to half the long-term average. Such changes are large, and there are no proxy data to support such extreme behaviour. Thus we consider that the  $\Delta^{14}\text{C}$  oscillations are best explained by solar-wind forcing.

Evidence of global solar change is provided by the 22-yr Hale (sunspot) cycle, from which a 90-yr (Gleissberg) periodicity has been deduced. Analysis of the number of aurorae reported per decade gives periodicities of 88 and 130 yr (refs 23, 24). The 88-yr periodicity is near the 85–87-yr period derived from the  $^{14}\text{C}$  data (Fig. 2), whereas the 130-yr period is close to the 127-yr period found for the 570 BC–AD 1830 interval. Our present analysis adds periodicities of about 140, 220 and 420 yr to these observations of solar patterns.

Solar-constant changes of up to 0.1% have been measured for the recent part of the Hale cycle<sup>25,26</sup>. Evidently the changes that result in sunspot and cosmic-ray modulation also induce changes in the solar constant. The longer periodicities of the  $^{14}\text{C}$  production record may also relate to such solar-constant change, and these changes may be larger in magnitude. If so, a relationship between climate and solar variability, as evidenced in the  $^{14}\text{C}$  record, is to be expected. Conflicting evidence exists for such a relationship<sup>27</sup>. Strong evidence for a correlation was given by Sonett and Suess<sup>22</sup> for a tree (bristlecone pine) ring-width record, for which periodicities of, for example, 114 and 208 yr were found.

Applying AR techniques to ten climate records (tree-rings and glacier fluctuations) reported by Röthlisberger<sup>28</sup>, we find that none of the spectra contain significant power in the range 200–250 yr. However, there is power in the 123–143-yr interval for six of the records, in the 102–104-yr range for three, and near 88 yr for two. In our previous study<sup>1</sup> of climate records covering only one millennium we found no convincing evidence for a Sun-climate relationship. The use of the much longer Röthlisberger records together with the  $^{14}\text{C}$  analysis reopens this question, and in particular there may be a Sun-climate relationship for the third harmonic (140 yr). □

ACID neutralizing capacity (ANC) is used to quantify the acid-base status of surface waters. Acidic waters have been defined as having ANC values less than zero, and acidification is often quantified by decreases in ANC. Measured and calculated values of ANC generally agree, except for low-ANC waters. These waters, however, are of primary interest in lake-acidification studies. The discrepancy in ANC values is greatest for waters with high concentrations of aluminium and/or dissolved organic carbon (DOC). The discrepancy due to aluminium increases with increasing concentration of dissolved monomeric aluminium ( $Al_m$ ) and can exceed  $50 \mu\text{eq l}^{-1}$  at low pH and high  $Al_m$  values. Here we show that this error can be minimized by using a proton reference level for aqueous aluminium of 2+, rather than 0 or 3+, as is done usually. The value of 2+ is consistent with the mean charge on aluminium at the equivalence point of strong-acid titrations. The discrepancy between calculated and measured ANC also increases with increasing DOC concentrations, exceeding  $50 \mu\text{eq l}^{-1}$  for waters with DOC concentrations greater than  $800 \mu\text{mol C l}^{-1}$  ( $1000 \mu\text{mol C l}^{-1} = 12 \text{ mg l}^{-1} \text{ DOC}$ ). This error can be decreased by titrating to a low consistent pH value (for example, 3.0). This reduces the systematic underestimation of ANC due to curvature in Gran<sup>1</sup> plot analysis, while still allowing accurate measurement of increments in hydrogen-ion concentration. ANC should not be used as a single parameter for characterizing the chemical suitability of surface waters for biota or for assessing the susceptibility of low-ANC waters to acidification by acid deposition.

In regional investigations of acid-base status, ANC has been the principal classification variable<sup>2</sup>. ANC is also widely used by simulation models that predict the response of ecosystems to changes in atmospheric acid deposition<sup>3–7</sup>. Historical changes in surface-water quality have been evaluated using measured changes in ANC<sup>8</sup> or estimated by inferring past and present pH and ANC from lake sediment diatom assemblages<sup>9,10</sup>.

ANC has also been used extensively to assess the susceptibility of surface waters to atmospherically derived strong acids<sup>11,12</sup>. Waters with high ANC values would generally be considered resistant to changes in pH resulting from changes in deposition acidity. Low-ANC waters may or may not resist changes in pH, depending on the processes supplying ANC in the terrestrial or aquatic environment<sup>13</sup>.

ANC has been used as a primary indicator of a water's suitability for aquatic biota. Other water-quality parameters, however, also need to be considered, including pH (ref. 14), inorganic monomeric aluminium<sup>14</sup>, and calcium<sup>15</sup>, as well as habitat characteristics (such as the availability of spawning substrate). In low-ANC waters, inorganic monomeric aluminium may constitute a large fraction of the non-hydrogen cations (see below) and thus be of biological significance.

ANC is a measure of the net strong base in solution. It is measured by quantifying the amount of strong acid that must be added to a solution to neutralize this base. The end point of this strong-acid titration would be easily identified except for the presence of weak acids and the relatively small amounts of strong base present in low-ANC waters. Together, these factors obscure the end point. For such systems, the Gran<sup>1</sup> procedure is most commonly used to determine the end point and therefore ANC.

ANC can be calculated by two distinct methods, which have been shown to be mathematically equivalent using the principles of conservation of charge and conservation of mass<sup>16</sup>. In one method<sup>17</sup>, ANC is calculated as the difference between the sum of the proton ( $H^+$ -ion) acceptors and the sum of the proton donors, relative to a selected proton reference level (discussed below):

$$\text{ANC} = [\text{HCO}_3^-] + 2[\text{CO}_3^{2-}] + [\text{OH}^-] + [\text{other proton acceptors}] - [\text{H}^+] \quad (1)$$

Here, square brackets denote molar concentrations. The other method relates ANC to the total non-hydrogen cation concentrations ( $M_T$ ; free and complexed forms); the individual uncomplexed cation charges ( $z_i$ ) at the equivalence point (the point at which, during titration, the concentration of proton donors equals the concentration of proton acceptors); the total strong-acid anion concentrations ( $A_T$ ; free and complexed); and the individual uncomplexed anion charges ( $z_j$ ), at the equivalence point (general theory<sup>16</sup>; practice<sup>18,19</sup>) using the following relation:

$$\text{ANC} = \sum_i^n |z_i| M_{T_i} - \sum_j^m |z_j| A_{T_j} \quad (2)$$

For aerobic surface waters the first term on the right hand side of equation (2) is typically approximated as

$$\sum_i^n |z_i| M_{T_i} \approx 2[\text{Ca}_T] + 2[\text{Mg}_T] + 2[\text{Mn}_T] + [\text{K}_T] + [\text{Na}_T] + [\text{NH}_4] + x[\text{Al}_T] \quad (3)$$

and the second term is approximated as

$$\sum_j^m |z_j| A_{T_j} \approx 2[\text{SO}_{4T}] + [\text{NO}_{3T}] + [\text{Cl}_T] + [\text{F}_T] \quad (4)$$

The charges  $z_i$  and  $z_j$  (and thus the concentration multipliers in equations (3) and (4)) are determined by the predominant charges of the uncomplexed constituents at the equivalence point.

For most of the species, there is little uncertainty as to the predominant uncomplexed charge at the equivalence point. For example, the charge of calcium is 2+, and thus the multiplier is 2 in equation (3). However, because of complexation with OH, F and organic ligands, the charge of aluminium, shown as  $x$  in equation (3), is not always obvious. Designation of this charge, however, establishes the proton reference level (PRL).

<sup>†</sup> Present addresses: E&S Environmental Chemistry, Inc., PO Box 609, Corvallis, Oregon 97339, USA and Environmental Research Laboratory—Corvallis, 200 SW 35th Street, Corvallis, Oregon 97333, USA.

PRL constituents do not change ANC but may change pH when added to waters isolated from soils and sediments<sup>20</sup>. In the literature<sup>5,18,19</sup>, two PRLs have been used for aluminium, 3+ and 0. These levels have different advantages; the former yields results that are closer to Gran ANC values; the latter eliminates the need to include aluminium in ANC calculations.

Data collected during the regionalized integrated lake-watershed acidification study (RILWAS)<sup>21,22</sup> from 25 lake-watershed systems in the Adirondack mountains of New York were used

FIG. 1 Mean charge of monomeric inorganic Al versus pH for RILWAS waters. Equivalence point of Gran titrations for dilute waters generally occurs in pH range 4.8 to 5.2. Here the equivalent charge of the aluminium is near 2+.

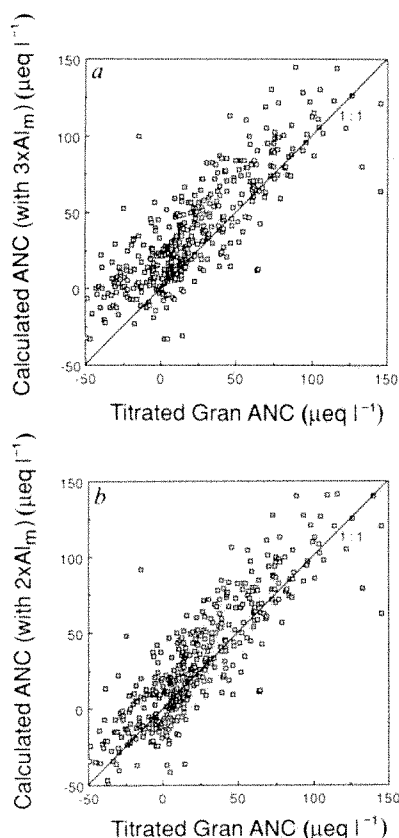

FIG. 2 Calculated ANC versus titrated Gran ANC for RILWAS lakes: Calculated ANC using a, proton reference level for  $Al_m$  of 3+ and b, proton reference level of 2+.

to estimate the aluminium PRL. The speciation of aluminium was calculated using the chemical equilibrium model ALCHEMI<sup>23</sup>, and the equivalent charge on the aluminium species was determined (Fig. 1). The mean charge on the aluminium increases with decreasing pH. However, over the pH range from 4.8 to 5.2, which corresponds to the equivalence point of dilute waters<sup>24</sup>, an aluminium charge of 2+ appears more representative than 3+ or zero. Moreover, Gran ANC more closely follows calculated ANC where two times  $Al_m$  is used in the calculation for RILWAS lakes (Fig. 2). This is equivalent to the PRL species for  $Al_m$  being  $Al(OH)^{2+}$  instead of  $Al^{3+}$  or  $Al(OH)_3^0$ .

The difference between calculated and measured Gran ANC values increases as organic-acid concentration, reflected by DOC, increases. This is evident in surface-water data for Meander Lake basin in northern Minnesota (Fig. 3). Meander Lake DOC values average only about  $400 \mu\text{mol C l}^{-1}$ , but one of the lake's inlets drains a spruce bog and contains DOC values as high as  $2,400 \mu\text{mol C l}^{-1}$  (ref. 13). Concentrations of aluminium in Meander waters are very low (mean  $Al_m = 1.3 \mu\text{mol l}^{-1}$ ). The discrepancy between calculated and Gran ANC can be as large as  $50 \mu\text{eq l}^{-1}$  at DOC concentrations of  $800 \mu\text{mol C l}^{-1}$ . A single maximum discrepancy of  $180 \mu\text{eq l}^{-1}$  was observed for a sample with  $2,400 \mu\text{mol C l}^{-1}$ .

To explore the DOC-related discrepancy, Gran analyses were performed on theoretical titration data. The Gran analysis of ANC titration data requires plotting the Gran function  $F_1$  versus titrant volume.  $F_1$  is calculated as follows:

$$F_1 = (V + V_0)10^{-pH} \quad (5)$$

where  $V$  is the added titrant volume and  $V_0$  is the original sample volume. This produces a curve like that shown in Fig. 4a. The right-most 'linear' portion of the curve is extrapolated to determine the equivalent volume of titrant, and thus the ANC of the sample.

The Gran analysis procedure was applied to data generated by performing computer-simulated titrations using equilibrium constants associated with the carbonate system<sup>17</sup>. In addition, a variety of monoprotic weak acids with varying concentrations and fixed strengths ( $pK_A$  values) were added to the solutions, one at a time, to simulate the effects of organic acids ( $6.5 \mu\text{eq mg}^{-1}$  DOC, which is close to that observed by others<sup>25</sup>). The initial ANC of each solution was set to  $50 \mu\text{eq l}^{-1}$ , and 100 ml aliquots of the solution were titrated with 0.01 M strong acid, in 20  $\mu\text{l}$  increments to pH 3. Table 1 shows the results of the Gran plot analysis using points from pH 3.0 to 3.3 for the extrapolation.

These values suggest that the difference between theoretical and Gran ANC due to the organic acid is <5%, at organic-acid

FIG. 3 The difference between calculated ANC (with 2 times  $Al_m$ ) and Gran ANC versus DOC for waters from the Meander Lake basin.

concentrations of  $0\text{--}25\ \mu\text{eq l}^{-1}$  ( $\sim 0\text{--}300\ \mu\text{mol C l}^{-1}$ ). At higher organic-acid concentrations the difference increases, reaching 28% at  $165\ \mu\text{eq l}^{-1}$  ( $2,100\ \mu\text{mol C l}^{-1}$ ). However, when these same synthetic titration data were analysed using a standard laboratory Gran analysis algorithm, the differences were larger. For an organic-acid concentration of  $25\ \mu\text{eq l}^{-1}$ , the difference was 10%, and it increased to 44% at  $165\ \mu\text{eq l}^{-1}$ .

The increasing curvature of the  $F_1$  function with increasing organic-acid concentration (Fig. 4b) can be problematic in analysis of titration data. The curve is nonlinear at much lower pH values (and thus higher  $F_1$  and  $V$  values) as the DOC concentration increases. If the titration is not carried out to a

FIG. 4 Analysis of curvature in the Gran procedure: a, illustration of a Gran plot. The linear portion of the curve is extrapolated to determine the equivalent titrant volume. The slope of the line should correspond to the normality of the titrant. b, Curvature in  $F_1$  Gran function due to organic acids. Curves are for carbonate solutions to which varying amounts of organic acid ( $pK_A = 4.5$ ) have been added ( $ANC = 50\ \mu\text{eq l}^{-1}$ ). At higher organic-acid concentrations, the curvature becomes more pronounced, and the intercept with the titrant volume axis shifts to lower values. c, Error in Gran ANC due to curvature of the  $F_1$  function versus DOC, for different final titration pH values. Number of points in the  $F_1$  Gran function used to extrapolate were 35 out of 75 (pH 4.0), 90 out of 190 (pH 3.5), and 300 out of 600 (pH 3.0). Failure to titrate to low pH values can lead to large errors in ANC.

TABLE 1 Gran analysis

Initial ANC ( $\mu\text{eq l}^{-1}$ )	Organic-acid concentration ( $\mu\text{eq l}^{-1}$ )	Organic-acid strength $pK_A$	Gran ANC ( $\mu\text{eq l}^{-1}$ )
50	0	—	50
50	25	6.5	50
50	50	6.5	50
50	25	5.5	49.8
50	50	5.5	49.5
50	25	4.5	47.9
50	50	4.5	45.7
50	75	4.5	43.6
50	100	4.5	41.5
50	165	4.5	36.0

low enough pH, the curvature will not be minimized and thus ANC will be underestimated (Fig. 4c). As indicated, the error in Gran ANC can exceed  $90\ \mu\text{eq l}^{-1}$  for high DOC waters owing to curvature in the  $F_1$  function alone, if titrations are only carried out to pH 4.0. The error decreases as the final pH of the titration decreases. Below pH 3.0, however, the error associated with the precise measurement of  $H^+$  concentration becomes too large to further improve Gran estimates.

These calculations indicate that the curvature error can range from 0 to  $90\ \mu\text{eq l}^{-1}$  for organic-acid concentrations of  $0\text{--}165\ \mu\text{eq l}^{-1}$  ( $0\text{--}2,100\ \mu\text{mol C l}^{-1}$ ). The actual differences observed in the Meander Lake basin waters were considerably larger. We hypothesize that the additional differences result from increasing strength of the acid functional groups as the solution  $H^+$  concentration increases. This type of behaviour has been observed<sup>26</sup> and has been attributed to protonation of adjacent functional groups of polyprotic organic acids<sup>27</sup>.

THE Black Sea is the largest anoxic marine basin in the world today<sup>1</sup>. Below the layer of oxygenated surface water, hydrogen sulphide builds up to concentrations as high as 425  $\mu\text{M}$  in the deep water down to a maximum depth of 2,200 m (ref. 2). The hydrographic regime is characterized by low-salinity surface water of river origin overlying high-salinity deep water of Mediterranean origin<sup>1,3</sup>. A steep pycnocline, centred at about 50 m is the primary physical barrier to mixing and is the origin of the stability of the anoxic (oxygen/hydrogen sulphide) interface. Here we report new observations, however, that indicate dramatic changes in the oceanographic characteristics of the anoxic interface of the Black Sea over decadal or shorter timescales. The anoxic, sulphide-containing interface has moved up in the water column since the last US cruises in 1969 and 1975. In addition, a suboxic zone overlays the sulphide-containing deep water. The expected overlap of oxygen and sulphide was not present. We believe that these observations result from horizontal mixing or flushing events that inject denser, saltier water into the relevant part of the water column. It is possible that man-made reduction in freshwater inflow into the Black Sea could cause these changes, although natural variability cannot be discounted.

The US-Turkish Oceanographic Expedition to the Black Sea consisted of five cruises on the RV *Knorr* from 15 April to 2 August 1988 (*Knorr* cruise 134, legs 8 to 12)<sup>4</sup>. One of the main goals was to study the anoxic interface in detail. The principal

features of the anoxic interface were summarized by Caspers<sup>1</sup>. Oxygen was found to be depleted to zero concentration at depths of between 125 and 300 m. During the RV *Atlantis II* cruise in March and April 1969 the boundary between the oxygenated surface waters and the sulphide-containing deep waters was found to occur along a constant-density horizon. An overlap of oxygen and sulphide of a few metres was observed<sup>2</sup>. The isopycnal surface (potential density,  $\sigma_\theta = 16.41$ ) of the oxygen zero boundary was dome-shaped and ranged from a depth of 115 m in the centre of the basin to about 275 m near the shelves<sup>3,5</sup>. The RV *Chain* visited the Black Sea in April 1975 and found hydrographic results that were nearly identical to those reported in 1969<sup>6</sup>. At that time the anoxic interface comprised a 20–30-m transition zone where oxygen and hydrogen sulphide coexisted at very low concentrations ( $<15 \mu\text{M}$ ) (ref. 7). Russian scientists have frequently reported the coexistence of oxygen and hydrogen sulphide in a zone called the 'C layer' (see, for example, ref. 8).

Several studies in the early 1980s<sup>8–12</sup> reported that the upper boundary of the sulphide zone was rising. We have confirmed such observations with high-quality continuous data and we find that the first appearance of sulphide in the water column is higher by as much as 30 m relative to the previous US studies in 1969 and 1975. In addition, we have also observed a significant gap of 10–40 m between the layer of oxygen decrease to suboxic levels (less than  $5 \mu\text{M}$ ) and that of the first appearance of hydrogen sulphide. This gap was thicker in the centre of the Black Sea than near its boundaries.

During the 1988 RV *Knorr* cruises we studied the chemistry and microbiology of the interface zone in detail using a new pump-profiling system. This pump sampler was attached to a CTD (conductivity, temperature and depth instrument) and interfaced to an autoanalyser for detailed analyses of  $\text{NO}_3^-$ ,  $\text{NO}_2^-$ ,  $\text{NH}_4^+$ ,  $\text{Si}$ ,  $\text{PO}_4^{3-}$  and  $\text{H}_2\text{S}$ . The pump was stopped at specific depths to collect samples for manual analyses. The pump was lowered at a rate of 6–10  $\text{m min}^{-1}$  and data were acquired every 3 s, giving a sampling rate of 2–3 data points per metre. Under calm conditions, features in the water column could be resolved to better than 2 m. Within less than an hour the detailed structure of the water column was characterized on a down cast and a discrete sampling strategy designed for the subsequent up cast.

The potential temperature ( $\theta$ ) in the central part of the western basin of the Black Sea (station BS3-2;  $32^\circ\text{E}$ ,  $42^\circ50'\text{N}$ ; 5 June 1988)<sup>13</sup> decreased from high surface values of  $>17^\circ\text{C}$ , reflecting seasonal warming, to a minimum of  $6.95^\circ\text{C}$  at 45 m, then increasing to  $8.58^\circ\text{C}$  at 100 m and to  $8.9^\circ\text{C}$  at 2,050 m (Fig. 1a). Station 1445 of the 1969 *Atlantis II* Black Sea cruise<sup>2</sup> ( $31^\circ27'\text{E}$ ,  $43^\circ08'\text{N}$ ; 1 April 1969) was in close proximity to our station BS3-2 and

FIG. 1 Potential temperature, salinity and density in the Black Sea. Open symbols are from station 1445 of the March 1969 *Atlantis II* Black Sea cruise. Closed symbols are from station BS3-2 of cruise 3 of the US-Turkish expedition (June, 1988). a, Potential temperature ( $\theta$ ) and salinity (S) plotted

against water depth to 200 m, calculated from SeaBird CTD data with the assistance of G. White and M. Relander. b, Potential temperature against salinity for the entire water column. c, Potential density ( $\sigma_\theta$ ) against water depth to 200 m.

is used for comparison. The 1969 and 1988 data agree well in the range from 50 m and 100 m and below 200 m. From 100 m to 200 m the 1988 temperature is about 0.1 °C warmer. The surface temperatures are quite different because the cruises were made at different times of the year.

The salinity in 1988 increased from 18.33‰ at the surface to 21.09‰ at 100 m (Fig. 1a) and then to 22.33‰ at 2,050 m. The 1969 data are sparse above 70 m, but the salinity was definitely higher by at least 0.1‰ in 1988 over the 50–200 m depth range<sup>3</sup>.

The change in hydrographic properties can also be seen by comparing plots of the potential temperature versus salinity ( $\theta$ - $S$ ) (Fig. 1b). There is clearly a departure toward higher salinities at a given potential temperature for salinities greater than 21.00‰. The net result is that the potential density ( $\sigma_\theta$ ) was higher from 50 m to 200 m by up to 0.3 in 1988. This corresponds to an upward shift of the isopycnal surfaces in this depth interval by as much as 20 m. In 1969 the  $\theta$ - $S$  diagram was linear across the anoxic interface from 50 to ~400 m. In 1988 the  $\theta$ - $S$  data were linear from about 45 m to 70 m, and there was a small degree of curvature through the anoxic interface region. Since 1969 (and 1975) there has been a small but significant change in the hydrographic and density structure of the anoxic interface region (50–200 m) at this location in the Black Sea.

In comparison with the subtle changes in the water-column hydrographic and density structure, the changes in the oxygen, sulphide and nutrient distributions have been more pronounced. The new data show that dissolved oxygen is high in the surface water with a photosynthetically produced maximum at 10 m (Fig. 2a). Oxygen concentration decreases rapidly, to values of less than 5  $\mu$ M at a depth of 55 m. In 1969 the measured oxygen concentration did not decrease to zero until about 125 m depth. Sulphide first appeared at about 95 m and increased almost linearly with depth (Fig. 2a). Repeat casts indicated that the uncertainty in this depth was about 5 m. This first appearance of sulphide occurred close to the density surface of  $\sigma_\theta = 16.32$ . In 1969 sulphide first appeared at 125 m, corresponding to the density surface of  $\sigma_\theta = 16.39$ . Thus sulphide appears to have shoaled slightly relative to the water-column density structure.

A prominent new feature in the anoxic interface is a suboxic zone that exists from 55 m to 95 m at station BS3-2. This zone is characterized by oxygen concentrations less than 5  $\mu$ M, with no discernible gradients. This suboxic zone was found at all stations occupied during the 1988 expedition and was unexpected, because most recent literature<sup>3,14,15</sup> reported the coexistence of  $O_2$  and  $H_2S$ ; the vertical extent of this coexistence

was reported to be as large as 90–100 m (ref. 15) and appeared to vary laterally and seasonally<sup>8</sup>. There is one earlier report of a suboxic zone but it appeared to be limited to an isolated eddy experiencing unusually intense vertical mixing<sup>16</sup>.

Ammonia content (Fig. 2b) increased rapidly and linearly with depth below 80 m. The gradient relative to depth for ammonia in 1988 was similar to that in 1969<sup>2</sup>, but was shifted upward by about 50 m in the recent data.

The 1988 phosphate profile (Fig. 2c) is intriguing because it shows a maximum at 55 m, decreasing to a minimum at 70 m, and then increasing rapidly to a large maximum at 95 m, coincident with the first appearance of sulphide. Similar profiles were found at most offshore stations. Examination of the 1969 data suggests that two  $PO_4^{3-}$  maxima were present but could not always be identified unambiguously because of the coarse sampling resolution<sup>14</sup>. The spline fit of the total 1969 data set used by Shaffer<sup>17</sup> showed that they were probably present. The upper  $PO_4^{3-}$  maximum is probably due to release from decomposing organic matter during aerobic respiration<sup>14</sup>. The deeper  $PO_4^{3-}$  maximum probably results from reductive dissolution of solid Mn and Fe oxides, which release adsorbed  $PO_4^{3-}$  (ref. 17). Both  $PO_4^{3-}$  maxima appear to have risen in the water column by about 50 m relative to 1969.

The changes in the salinity and density structure may reflect horizontal mixing or flushing events that inject new water into the pycnocline. Several authors have proposed that the pycnocline is most probably influenced by lateral ventilation rather than by one-dimensional vertical transport (see, for example, ref. 18). The shallow temperature minimum bounded by the 8 °C isotherms is called the cold intermediate layer (CIL). At station BS3-2 the CIL is between 25 and 55 m. Tolmazin<sup>19</sup> has summarized the evidence (for example, ref. 20) to suggest that the water in the CIL originates in the Northwestern Shelf (NWS) region of the Black Sea. Here, the coldest temperatures and low river runoff in winter result in the formation of dense water which descends the slope and spreads across the rest of the Black Sea on a timescale of about one year. Ovchinnikov and Popov<sup>21</sup> have recently proposed the alternative view that the water in the CIL originates at the centres of the cyclonic gyres.

Regardless of the origin of the water in the CIL, its production rate and density must be closely linked to long-term variations in the freshwater and heat budgets of the Black Sea. When very dense water forms, the flow overshoots the traditional lower boundary of the CIL. Natural interannual or decadal variations in climate and river runoff can produce horizontal temperature and salinity (that is, density) waves in this shallow intermediate

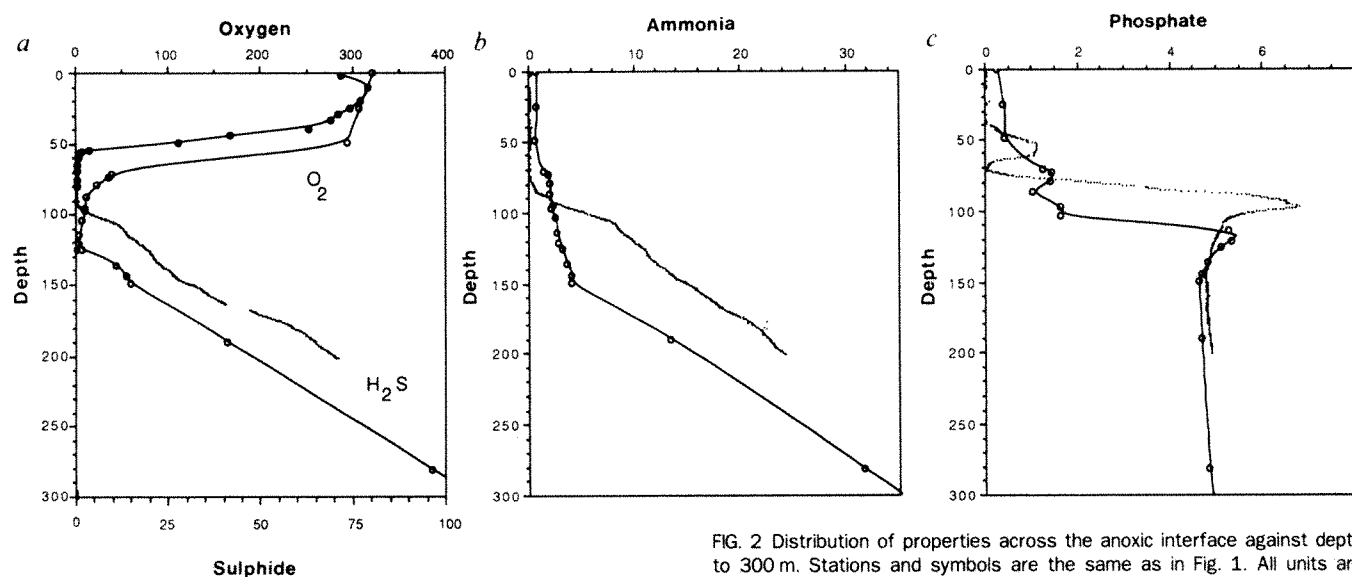

FIG. 2 Distribution of properties across the anoxic interface against depth to 300 m. Stations and symbols are the same as in Fig. 1. All units are  $\mu$ mol kg<sup>-1</sup>. a, Oxygen and hydrogen sulphide. b, Ammonia. c, Phosphate.

layer. Superimposed on these natural variations is the man-made reduction in the freshwater runoff from Soviet rivers entering the NWS region of the Black Sea. Tolmazin<sup>19,22</sup> reported that river flow of the Dnieper and Dniester had already been reduced by 50% in 1981. The total freshwater input from all rivers had been reduced by about 15%. Reduction in river input will also result in increased Mediterranean sea-water input through the Bosphorus<sup>23</sup>. Substantial reduction in freshwater influx should cause changes in the salinity structure of the upper layer of the Black Sea. The extreme case of no river input would eventually result in a Mediterranean-style circulation for the Black Sea.

Our data clearly show that the salinity and density in the depth range 50–200 m was high in 1988 relative to historical values. It is possible that a reduction in the freshwater inflow is resulting in the formation of intermediate waters that have higher salinities and densities than in the past. The data set is not complete enough, however, to allow us to distinguish man-made effects from possible natural variations.

Increased production of water to the shallow intermediate layers could be viewed as analogous to the mixing or flushing events that occur in other anoxic basins, such as Saanich Inlet<sup>24–26</sup> and the Baltic Sea<sup>27</sup>. These flushing events produce suboxic zones similar to the one recently observed in the Black Sea. Flushing is thought to displace anoxic water upward in the water column. The sulphide in this displaced water then reacts with oxygen to form an oxygen-depleted layer<sup>28</sup>. Any remaining oxygen is then consumed by aerobic respiration, thus producing a suboxic layer.

Additional chemical and microbiological results will need to be considered for a complete description of the changes in the

oxic/anoxic interface. The flushing-event hypothesis is attractive, however, because it can simultaneously explain the changes in salinity, density and concentration of oxygen, sulphide and nutrients. □

## Static amorphization of anorthite at 300 K and comparison with diaplectic glass

Quentin Williams\* & Raymond Jeanloz

Department of Geology and Geophysics, University of California, Berkeley, California 94720, USA

DIAPLECTIC glass, which is produced without fusion, is characteristic of meteorite impact sites in feldspar- and quartz-rich sites on the Earth and Moon; it has also been produced in laboratory shock experiments<sup>1–3</sup>. Its presence in nature is thus considered to be strong evidence of exposure to a high-pressure shock wave generated by impact. The formation of such glasses has been universally interpreted in terms of the brief, high-temperature and high-pressure conditions characteristic of shock loading. Here we report that crystalline anorthite ( $\text{CaAl}_2\text{Si}_2\text{O}_8$ ) becomes amorphous at static pressures of between 22 and 28 GPa at 300 K. The amorphization is associated with a pressure-induced increase in the coordination of silicon and aluminium by oxygen, from fourfold to five- and sixfold. The increase in coordination appears as the sample vitrifies at pressure; on decompression, the coordination reverts to fourfold. The vitrification is spatially heterogeneous, and may be crystallographically controlled. The formation of glass from crystalline material under static conditions at 300 K indicates that the high strain rates and temperatures associated with shock compression are not required for the creation of glasses without fusion.

The starting material used in this study is 'transitional' anorthite from Miyake-zima, Japan, and is identical to the sample material used in previous shock experiments<sup>4</sup>. Single crystals of this material, each about 15  $\mu\text{m}$  in thickness, were

statically compressed in a Mao-Bell-type diamond cell; pressures were determined using ruby fluorescence<sup>5</sup>. A 16:3:1 mixture of methanol, ethanol and water was used as a pressure-transmitting medium, as this mix is hydrostatic to pressures of 15 GPa (ref. 6). At higher pressures, the samples were sufficiently small that the pressure gradients across them did not exceed 1 GPa. In particular, samples never bridged the gap between the diamond anvils. Pressures were increased over about 10 minutes, and the samples were then held at each pressure for approximately 18 hours, which is about 11 orders of magnitude longer than the corresponding periods in shock experiments. High-pressure infrared spectra were measured using a technique described elsewhere<sup>7</sup>, and indices of refraction were measured by the oil-immersion technique at ambient conditions.

Figure 1a shows a single crystal of anorthite before compression. The sample is optically anisotropic, with a birefringence of 0.013, in accord with the typical value for such crystals<sup>8</sup>. Samples compressed to 15 GPa exhibit no evidence for vitrification, nor any departure from single-crystal characteristics. After compression to 22 GPa, however, two optically isotropic bands appear in the sample (Fig. 1b). Each of these is about 20  $\mu\text{m}$  wide, and they have a separation of about 40  $\mu\text{m}$ . The birefringence of the crystalline material is indistinguishable (to within 20%) from that of the starting material. After compression to 28 GPa, the sample is optically isotropic, with a birefringence of less than 0.002 (Fig. 1c). Thus, crystalline anorthite is transformed to a glassy state merely by static compression to pressures exceeding 25 ( $\pm 3$ ) GPa, at ambient temperature.

The index of refraction of a quenched isotropic sample of anorthite glass is 1.62 ( $\pm 0.02$ ), significantly higher than the mean value of 1.58 observed for both anorthite crystal and shock-produced anorthite glass<sup>9</sup>. Thus, it seems that the amount of time over which a sample is compressed, and possibly the post-shock thermal regime, may profoundly affect the degree of densification within pressure-amorphized silicates. Comparisons between glasses formed by shocks of different duration might not, therefore, yield reliable estimates of peak shock pressures.

\* Present Address: Institute of Tectonics, Board of Earth Sciences, University of California, Santa Cruz, California 95064, USA.

FIG. 1 Anorthite sample at zero pressure (outside the diamond cell) photographed with cross-polarized transmitted white light passing through a gypsum plate: *a*, before compression, *b*, after compression to 22 GPa, and *c*, after compression to 28 GPa. The sample is approximately 15  $\mu\text{m}$  thick and each scale bar is 50  $\mu\text{m}$  long. The multiply compressed sample fractured between photographs, but it is shown in the same orientation and arrows indicate the same feature in *a* and *c*. The two arrows in *b* indicate the vertically oriented isotropic bands that formed at high pressure. Note that the colour of the transmitted light is identical to the background colour in *c*, indicating that the sample is isotropic, except where small grains of ruby (used for pressure calibration) lie on its surface.

To determine the mechanism of the vitrification process, one must examine the microscopic structure of the sample as it amorphizes. Pressure-induced amorphization of two polymorphs of  $\text{SiO}_2$ , quartz and coesite, has been documented by Raman spectroscopy and X-ray diffraction<sup>10,11</sup>. As this amorphization involves the disappearance of both the X-ray diffraction pattern and, at higher pressures, the Raman spectrum, little information was obtained about the molecular-scale structure of the high-pressure amorphous phase. In contrast, infrared absorption spectra may characterize anorthite both before and after amorphization.

Figure 2 shows infrared spectra of initially crystalline anorthite as it is compressed to 1.7 GPa and 33.4 GPa, and then decompressed to 1.0 GPa. The strong absorption bands between 850 and 1,200  $\text{cm}^{-1}$  in the low-pressure spectra of anorthite are due to antisymmetric stretching vibrations of both the  $\text{SiO}_4$  and the  $\text{AlO}_4$  tetrahedra<sup>12</sup>. The intensity of these tetrahedral bands is decreased significantly in the spectrum of anorthite at 33.4 GPa, and there is an increased amplitude in the spectral region between 700 and 900  $\text{cm}^{-1}$ . Although anorthite undergoes a symmetry-lowering phase transition at 2.7 GPa (ref. 13), the effect of this structural change on the vibrational spectrum is small (Q.W. and R.J., unpublished results). Absorption between 700 and 900  $\text{cm}^{-1}$  is characteristic of silicon-oxygen and aluminium-oxygen polyhedra with octahedral and distorted octahedral coordination<sup>7,14</sup>. At 33.4 GPa, the broadening of the bands and the appearance of new bands in the spectrum, combined with our optical microscopic studies, indicate that the sample has become amorphous at this pressure<sup>15</sup>. In the spectrum of decompressed anorthite, the tetrahedral peaks have returned to their initial amplitude but the entire spectrum is broader and more poorly resolved than that of the starting material. This demonstrates, in accord with our optical observations, that the quenched sample is amorphous. Thus, the initially fourfold-coordinated crystalline anorthite is transformed under pressure to a glass with an increased coordination of aluminium and silicon. This densified, highly coordinated glass subsequently reconverts to a tetrahedrally coordinated glass on decompression. Such reversible transitions from fourfold to sixfold coordination of silicon and aluminium have been observed at 300 K within a glass of anorthite composition at pressures above  $\sim 11$  GPa (refs 7, 15).

Four mechanisms have been proposed previously for the creation of diaplectic glass: (1) reversion from a crystalline high-pressure phase on pressure release, (2) localized melting in 'shear bands', (3) defect-mediated amorphization, and (4) formation of a high-density glass under pressure. The first of these presumes that a crystalline high-pressure phase is formed under shock, which then reverts to glass during the high-temperature release from the shocked state. This model was proposed primarily because the density of framework silicates is large under shock compression, and it explicitly assumes thermodynamic equilibrium in the shocked state<sup>16</sup>. For com-

parison, the equilibrium crystalline assemblage of anorthite composition at pressures above 15 GPa is a three-phase mixture of  $\text{CaSiO}_3$ -perovskite, corundum and stishovite<sup>17</sup>. The amorphization that we observe is completely distinct from a transition to these phases, however. Moreover, corundum and stishovite are quenchable down to 1 bar pressure, yet are not present in our decompressed samples. Thus, we conclude that the transition to an amorphous state occurs under pressure as a non-equilibrium, kinetically hindered process.

Formation of diaplectic glass by local melting in shear zones—regions of high temperature created by intense deformation at high strain rates—has been proposed on the basis that shock deformation is spatially heterogeneous<sup>9,18–21</sup>. Both theoretical and empirical results support the shear-band model of shock deformation, but no correlation with glass formation has been demonstrated. Because neither high strain rates nor high temperatures are involved in glass formation in these experiments, we conclude that neither of the first two models, post-shock reversion of a high-pressure crystalline phase and localized melting in shear bands, satisfactorily explains the formation of pressure-induced glasses.

The last two mechanisms—defect-mediated processes (perhaps involving high dislocation densities) and direct conversion of low-pressure framework silicates to denser glasses under pressure—are both plausible means of amorphization<sup>3,22–24</sup>. These mechanisms of glass formation are not mutually exclusive, and they are supported by our observations. For example, the infrared spectra indicate that the coordination of aluminium and silicon increases at high pressures; the more highly coordinated species must, when present in small concentrations, constitute defects in the feldspar structure. Neither of these mechan-

FIG. 2 Infrared absorption spectra of anorthite at 1.7 GPa (top), at 33.4 GPa (middle), and on subsequent decompression to 1.0 GPa (bottom), all at 300 K.

isms, however, predicts explicitly the spatially abrupt transition that we observe between crystal and glass<sup>21-25</sup>. If defect generation (or increases in coordination) were homogeneous within the sample, amorphization would be expected to constitute a macroscopically uniform transformation. In this context, our observation that the amorphous regions are initially confined to sharp bands within the crystalline material affords an interesting comparison with shock-generated diaplectic glasses (Fig. 1b). Anorthite samples recovered from shock pressures of 30 GPa contain planar, crystallographically oriented lamellae of glass, juxtaposed with crystalline anorthite<sup>25</sup>. Although the features observed in the shock-compressed samples are typically of sub-micrometre size, the planar features observed in our sample may be of similar origin. We speculate that, following the deformation of a tetrahedron or the collapse of a ring of tetrahedra to more highly coordinated species, subsequent deformations are controlled crystallographically and nucleate preferentially near the initial defect.

The mechanism proposed here by which crystalline feldspars are converted, via an amorphous, highly coordinated structure, to a glass provides a plausible explanation for the lack of significant argon loss from feldspars during the shock-loading process<sup>26,27</sup>. Such loss has been reported when the sample melts under shock, as is expected in the shear-band model of diaplectic-glass generation, or at pressures above about 50 GPa, for which melting of feldspars is inferred to occur<sup>23,24</sup>. In the formation mechanism proposed here, the coordination of the glass changes but there is little diffusional motion, and the transformation proceeds entirely in the solid state. Thus, we would expect shock-loading itself to induce little argon loss in feldspars at pressures under 50 GPa, although high post-shock temperatures may cause significant loss at lower pressures<sup>26</sup>.

In the case of SiO<sub>2</sub>, the properties of glassy and crystalline silica are such that the free energies of the ordered and disordered phases become similar at the pressure at which amorphization occurs. Thus, it has been proposed that the transition from high-pressure crystal to amorphous solid is described quantitatively by (metastable) equilibrium thermodynamics<sup>11</sup>, with kinetic effects preventing formation of the stable crystalline phase(s). An analysis of the relative stabilities of anorthite and anorthite glass is consistent with our observations: using available elastic and thermodynamic properties<sup>13,28-30</sup> and assuming a value of 4 for the derivative of the bulk modulus with respect to pressure for each phase, we predict a pressure of 28 GPa for the crystal-to-amorphous transition in CaAl<sub>2</sub>Si<sub>2</sub>O<sub>8</sub>. Because the elastic properties of anorthite glass are poorly constrained<sup>29</sup>, however, the agreement of this prediction with our observations may be fortuitous. Moreover, it is possible that non-hydrostatic stresses play a role in determining the pressure and temperature range, and perhaps even the occurrence, of this crystal-to-glass transition. We cannot preclude this possibility, but are unable to resolve such effects on the amorphization pressure. As the shocked state is also heterogeneous, with local regions of high differential strain<sup>19</sup>, we conclude that the different states of stress and strain rate in shocked and statically compressed samples are not significant in the formation of diaplectic glass.

The inferred coordination changes in these metastably compressed silicates probably involve significant density increases. Large increases in density are observed on the Hugoniot shock-compression curve at those pressures at which diaplectic glass is formed<sup>16,31</sup>. We therefore attribute the observation of a densified, mixed-phase regime along the Hugoniot of silicates<sup>16,31,32</sup> to the presence not of coexisting low- and high-pressure crystalline phases, but of a mixed-coordination glass created by shock-loading. This is supported by the extreme difficulty in quenching crystalline high-pressure phases from Hugoniot conditions<sup>33,34</sup>.

The presence of diaplectic glass in natural samples has long been interpreted as field evidence for impact-induced shock-loading. Although our results show that diaplectic-like glass can

be formed statically, we emphasize that the high pressures and relatively low temperatures at which this transition takes place are unlikely to be brought about by any known tectonic or volcanic process, whether in subduction zones<sup>35</sup> or explosive eruptions<sup>36</sup>. Thus it remains probable that such glasses are formed naturally only by impact-induced shock compression.

## Carbonate melt from the mantle in the volcanoes of south-east Zambia

D. K. Bailey\*

Department of Geology, University of Reading, Whiteknights, Reading RG6 2AB, UK

RECENTLY Wallace and Green<sup>1</sup> reported the experimental formation of a dolomitic (Ca-Mg) carbonate melt in equilibrium with peridotite minerals in the range 21-30 kbar and 930-1,080 °C. These results confirm earlier deductions that, in the presence of CO<sub>2</sub>, initial melts from the mantle would be carbonatitic<sup>2,3</sup>, and extend the conditions of carbonate melt generation. The dolomitic melt composition also endorses earlier observations of quench dolomite after experimental melting of a natural garnet peridotite<sup>4</sup>. Dolomitic ashes, erupted from volcanoes near the confluence of the Rufunsa and Luangwa rivers in south-east Zambia<sup>5,6</sup>, offer the nearest analogue to the experimental melt yet reported. Quenched melt droplets in the volcanics now reveal new evidence indicating a mantle source for this natural dolomite liquid. Specifically, I present here results which show that the liquid contains magnesiochromite crystals (52% Cr<sub>2</sub>O<sub>3</sub>) that match those in mantle peridotites, kimberlites and lamproites. In contrast with the experimental liquid, the natural dolomitic melt has a low iron content,

\* Address from July 1989: Department of Geology, University of Bristol, Wills Memorial Building, Queens Road, Bristol BS8 1RJ, UK.

and high manganese and strontium, with alkalis virtually absent. High potassium activity is recorded, however, in the intensely metasomatized rocks around the main volcanoes. These differences suggest that the mantle source region chemistry differs from the high-sodium source envisaged in the experiments. The Zambian carbonatites thus reveal new aspects of carbonate melt and fluid activity in the Earth's mantle.

Volcanism in the Rufunsa region was approximately contemporaneous with the Chilwa Alkaline Province in Malawi (early Cretaceous, 135–105 Myr ago)<sup>7</sup>, and during the activity the three major centres were intruded by coarse-grained carbonatites, similar in all essentials to the classic intrusive complexes of Chilwa and elsewhere<sup>8</sup>. At Rufunsa, however, the intrusions were pierced by eruptions of pyroclastic dolomitic carbonatite unique to this locality. Sub-aerial volcanics of the same composition are preserved around the two southernmost complexes. Widely scattered smaller vents, ranging in size down to a few metres across, are filled solely with dolomitic tuffsite which is in most cases the product of a single eruptive episode. All the volcanological features indicate diatreme eruption through the crust by high-velocity, particle-charged streams of melt or fluid. Alkaline silicate magmatism (which normally accompanies carbonatite activity) is absent from the Rufunsa volcanism; this too is consistent with eruption directly from the site of melt formation. Activity was clearly localized by the intersection of the Luangwa and lower Zambezi rifts (Fig. 1). Rift intersections provide favourable sites for alkaline and carbonatite magmatism in continental interiors<sup>9,10</sup>, where the complex stress field favours perforation of the crust by deep-seated magmatism. Both the volcanology and the tectonics therefore point to high-speed eruption of the Rufunsa carbonatite volcanics directly from the mantle<sup>5,6</sup>. Eruption speeds for CO<sub>2</sub>-rich (diatreme-forming) melts from the mantle have been calculated by different methods<sup>11–13</sup>, and values of around 70 km h<sup>-1</sup> are 'generally regarded as reasonable'<sup>12</sup>. Solids would be entrained in a melt,

or fluid, or in melt + fluid, the appearance of fluid being strongly system-dependent<sup>14</sup>.

A striking example of the carbonatite tuffsite is preserved as one of the final eruptions through the axial zone of the Chasweta volcano. The rock is a mixture of angular accidental fragments (from the vent walls) and clear, rounded lapillae, in a dark red, fine-grained matrix (Fig. 2). Some lapillae have droplet shapes, and similar clear material also appears in intricate curved wisps and crescentic forms. Many lapillae enclose accidental fragments, typically of barite, coarse carbonate or feldspar. As with the other lapillae, the enclosing jackets consist mainly of very fine-grained colourless carbonate, with textures ranging from interlocking granular to trachytic. Deposition of carbonate melt on high-level accidental fragments is consistent with the proposal that separation of carbonate melt and fluid may occur only as the eruption nears the surface<sup>14</sup>. At this point, separated melt could be quenched almost instantaneously in supercooled fluid, which would explain the preservation of fragile melt wisps. The quenched melt is largely Mn- and Sr-rich dolomite (Table 1, column 3), whereas the surrounding matrix is iron-oxide-rich, implying that iron was strongly segregated into the transporting fluid phase. In most of the carbonate analyses, alkalis were either not detected or were present close to the detection limit.

Probably the most remarkable finding in the microprobe examination of the carbonate lapillae was the presence of chrome-rich spinel. The same mineral is found also in the intrusive tuffsites of Mwambuto, the major volcanic centre to the west of Chasweta. The spinel is dispersed as minute octahedra (<100 µm) through the carbonate; its distribution, euhedral form and the strong chemical zoning (Table 1, columns 4 and 5) indicate crystallization from the carbonate melt, probably on the liquidus. It has generally been accepted that 'carbonatites are not chromium-rich'<sup>15</sup>; one published average<sup>16</sup>, for example, gives a Cr content of 66 p.p.m., compared with 117 p.p.m. for average igneous rock. (Rufunsa melt lapillae have an estimated Cr content of around 1,000 p.p.m.) The Rufunsa volcanics are the first recorded instance of magnesiochromite-bearing carbonatite melt. For carbonatites worldwide, the spinel always hitherto reported is magnetite<sup>17</sup> (which has a very low Cr content). At Rufunsa, magnetite is common in the coarse-grained intrusive carbonatites, emphasizing that the magnesiochromite-bearing pyroclasts are not simply volcanoclastic equivalents of normal carbonatite but must have a different origin. Chrome-rich spinels of this composition are typically associated with ultramafic rocks of high-pressure origin, the compositions in Table 1 matching those reported from mantle xenoliths in kimberlites<sup>18,19</sup>. The compositions found are the same as early-crystallizing spinels both in kimberlites them-

FIG. 1 Sketch map showing the intersection of the Luangwa (north-east-south-west) and Lower Zambezi Rift zones (rift depressions largely marked by sediments younger than 208 Myr (stipple), with older crystalline rocks (blank) forming higher ground); based on sheet 5 of ref. 29. The three main Rufunsa carbonatite volcanoes are indicated by filled circles. Sample H.780 comes from the vent of the most south-easterly volcano, Chasweta. The confluence of the Luangwa and Zambezi rivers marks the common border point of Zambia, Zimbabwe and Mozambique.

FIG. 2 Photograph of a thin section of the carbonatite volcanic in the vent of the Chasweta volcano. The rounded clear fragments are chilled carbonate melt droplets. Field of view is 3.4 mm wide.

selves<sup>20</sup> and in the 'group 1' spinels of lamproites<sup>21</sup> (both magma types may be diamondiferous and hence of mantle origin). Two other characteristics of the Rufunsa spinels confirm their high-pressure source. Haggerty<sup>19</sup> points out that low-pressure spinels are marked by higher levels of Ti and Fe<sup>3+</sup>, both of which are very low in the Rufunsa spinels. More importantly, he notes that spinels from the deepest mantle samples show a trend of falling Cr and rising Al with decreasing pressure and temperature, which is precisely the trend from core to rim in Rufunsa spinels. Rapid ascent of the Rufunsa melt, carrying the earliest-formed spinels, would provide such conditions of falling pressure and temperature, which are now recorded in the outer zones of the crystals by falling Cr and rising Al.

The association of carbonatites with mantle-derived magmas such as nephelinites, melilitites and kimberlites (which themselves may carry mantle xenoliths) puts their ultimate mantle source beyond question. In the Rufunsa province it is deduced, on the following grounds, that the carbonatite pyroclasts were erupted directly from the mantle source: (1) Rift intersection tectonics and diatremic style of eruption are consistent with direct tapping of the mantle<sup>5,6</sup>; (2) The dolomitic composition is that predicted by experiment for carbonate melts from a high-pressure peridotite source<sup>1,4</sup>; (3) The presence of magnesiochromite emphasizes the ultramafic connection; (4) Magnesiochromite compositions completely match those of high-pressure mantle rocks and accepted mantle melts (kimberlites/lamproites); (5) Zoning in the magnesiochromite is consistent with crystallization under conditions of falling *P* and *T* during magma ascent from the mantle source.

Attention has been drawn previously to the lack of sodium minerals in the Rufunsa volcanism<sup>6,22</sup>, the only alkali silicates in these volcanics being the K-Mg mica, phlogopite, and pure potash feldspar<sup>6</sup> (Table 1, columns 7 and 8). Both minerals are contained in fragments of metasomatized wall rocks. Phlogopite is very abundant in some eruptives, pointing to a greater abundance at depth and to the likelihood that the carbonatite melt source would have had phlogopite, rather than amphibole, as the major alkali-bearing phase. Experiments show that Mg-

FIG. 3 Scanning electron microscope (back-scatter) image of a polished section of sample H.780, showing euhedral, zoned magnesiochromite in a carbonate matrix (analyses in Table 2). Scale bar, 10  $\mu$ m.

bearing carbonate melts must be expected from a phlogopite-bearing mantle<sup>23,24</sup> at depths below the amphibole stability region<sup>1</sup>, but analysis of the minute near-solidus liquids has not yet been possible.

For a more complete picture of the magmatic chemistry one must combine the melt composition, as revealed in the lapillae, with available data on the fluids in the system. In the dark red matrix of the volcanics, the iron content (as Fe<sub>2</sub>O<sub>3</sub>) may be as high as 10%, which must be ascribed largely to the transporting fluid, as no known country rock could provide an adequate source by contamination. Around the main vents, where there was sustained activity, potassium metasomatism affects all wall rocks regardless of initial composition, and its ultimate source must be in the magma system. Late fluids rich in Ba, P, S and F also cut all earlier rocks in the volcanoes. The total primary carbonatite budget should therefore include Mg, Ca, Mn, Sr, CO<sub>2</sub>, P, Al, Cr and Fe in the melt, and K, Fe, Ba, S, P and F partitioned into fluids at lower pressure. Of these, only Mg and Cr (and possibly Al) would be expected in higher concentrations in the source mantle; all the other elements must be regarded as strongly partitioned from the source mantle into the carbonatite. Separation of melt and fluid at low pressures means that only the broad attributes of the total chemistry may be accessible from the volcanic system, but even this initial assessment reveals some remarkable parallels with melt inclusions in diamonds<sup>25</sup>. Most notable in this respect is the balance of Ca and Mg, and the high levels of K, Fe, Ba and Sr in the diamond inclusions. Clearly, the Rufunsa carbonatites point the way to a new understanding of melt/fluid processes in the mantle.

There are many links between carbonatites and kimberlites, and in a few cases there are records of the presence of diamonds in the carbonatite association (refs 26, 27 and M. S. Garson, personal communication). It should be noted that kimberlites (of uncertain age) are also found along the Luangwa rift zone<sup>28</sup>, some about 400 km to the south-west in Zimbabwe and some (diamondiferous) about 400 km to the north-east in Zambia. Typical indicator minerals of kimberlite, such as picro-ilmenite and pyrope, were not sought in the original survey of Rufunsa, when the chief economic targets were Nb and P mineralization. In view of the mantle origin of the carbonatite volcanics, however, the possibility cannot be excluded that the Rufunsa volcanics may themselves contain diamonds. □

TABLE 1 Carbonatite volcanic rock (H.780) and constituent minerals compared with experimental run products (\*) at 22 kbar pressure and 1,000 °C

## Mate guarding as paternity insurance in Idaho ground squirrels

Paul W. Sherman

Section of Neurobiology and Behavior, Seeley G. Mudd Hall, Cornell University, Ithaca, New York 14853, USA

FOLLOWING a copulation, males in many species of vertebrates (particularly birds)<sup>1-4</sup> and invertebrates<sup>5,6</sup> remain near the inseminated female and repel other suitors with displays or force. Guarding males must delay resumption of competitive mate searching<sup>7</sup>, but they may insure their paternity by reducing possibilities for secondary matings and sperm competition<sup>8,9</sup>. Among mammals, post-copulatory mate guarding has been reported in rodents<sup>10-12</sup>, mongooses<sup>13</sup>, ungulates<sup>14,15</sup> and primates<sup>16,17</sup>, including humans<sup>18</sup>, but the effects of such behaviour on male reproductive success have not been determined genetically. I report here that mate guarding by male Idaho ground squirrels (*Spermophilus brunneus*) enhances a male's probability of paternity. Furthermore, an analysis based on game theory shows that mate guarding is an evolutionarily stable strategy for male *S. brunneus*, but not male Belding's ground squirrels (*S. beldingi*), which resume searching once copulation is completed.

The Idaho ground squirrel is the rarest and least known of the 18 North American *Spermophilus* species. It is endemic to an area of only ~8,000 km<sup>2</sup> in west-central Idaho, and the population is divided into small demes (many with <300 animals)<sup>19</sup>. During 1987 and 1988 I studied a deme of ~100 individuals located in a short-grass meadow at 1,870-m elevation (45°00' N, 116°40' W), 34 km northwest of Council, Idaho. Ground squirrels there are diurnally active for just over 4 months in the year, emerging from hibernation in late March and disappearing again by early August.

Every ground squirrel in the study population was marked with black hair dye for visual recognition and with eartags for permanent identification. The sexual behaviour of ground squirrels was observed on 13 days in 1987 (between 31 March and 14 April) and on 12 days in 1988 (4-17 April), for a total of 228 man-hours. Females were sexually attractive to males for only a few hours on the first or second afternoon following their emergence from hibernation. Newly emerged females remained near their hibernacula, where they were located and courted by adult males (≥2 years old), who themselves had emerged 1-2 weeks previously.

Copulations occurred below ground and so were not observable. Matings were inferred when four criteria were met<sup>20</sup>: male (1) followed a female closely and sniffed or licked her genitalia, then (2) accompanied her into a burrow, where (3) the pair remained for >5 min, after which (4) a sperm plug was observed in the female's vagina<sup>21</sup>. These criteria were fulfilled for each female on only one afternoon in the year, and pup invariably appeared above ground 50-52 days later. Thus I am confident that a female's oestrus and her copulatory behaviour were appropriately interpreted.

By watching continuously I recorded all male attendants to and presumed copulations of, 12 females in 1987 and 14 female in 1988. Following matings, males stayed close to females: male was ≤1 m from each focal female in 87% ± 15% (s.d.) of scan samples taken every 30-45 min after a female's first mating (total scans = 179). A given male attempted to keep his mate in a small area by herding, and he often followed her down burrow then immediately re-emerged and blocked the entrance with his body. If a guarding male temporarily lost contact with his female (for example, if she went into a burrow unobserved) he gave a staccato chirping vocalization until she was relocated

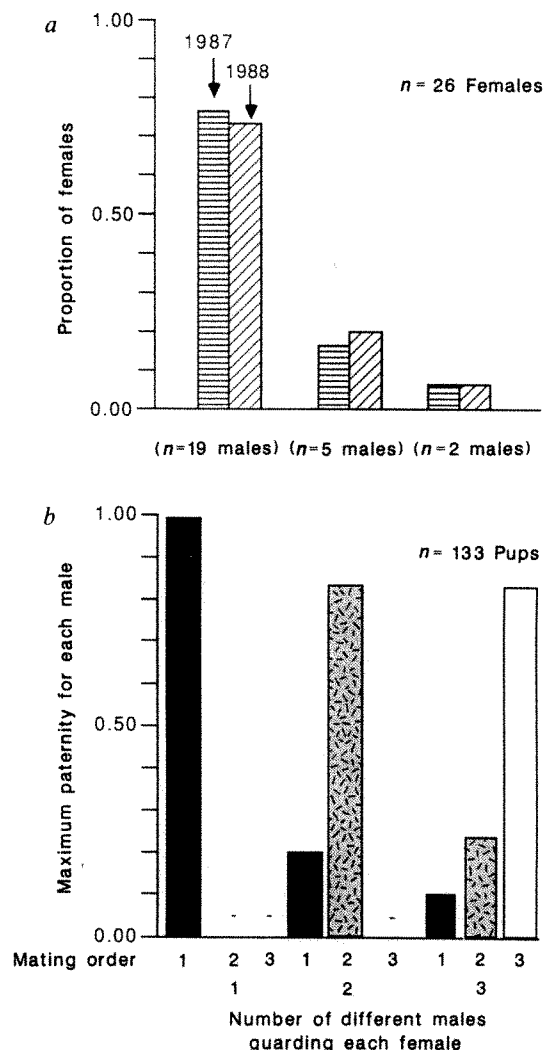

FIG. 1 *a*, The number of different males that guarded and apparently mated with 26 focal female Idaho ground squirrels (*S. brunneus*) in 1987 and 1988. *b*, Results of the electrophoretic paternity exclusion analyses, showing the highest proportion of the total offspring born to focal females that could have been sired by each successive guarding male (sample sizes are 97, 27 and 9 pups born to females guarded by 1, 2, and 3 males, respectively; data from 1987 and 1988 are combined).

the 'lost female' call was heard only in this context. Consort pairs went underground together every  $39 \pm 20$  min. and spent  $9.4 \pm 1.3$  min there. I captured 11 pairs the first time they resurfaced, and eight of the females had fresh vaginal plugs, indicating a recent copulation.

When a conspecific male approached a consort pair, the guarding male attacked him. In 72% of approaches ( $\leq 3$  m;  $n = 57$ ) the intruder fled, whereas in 28% he remained and fought. Usually males successfully sequestered their mate: of the 26 focal females, 19 were guarded by only one male and seven were guarded sequentially by multiple males (Fig. 1a). Guarding lasted  $2.9 \pm 1.1$  h regardless of the number of males involved, and terminated only when females were no longer approached by rival males (that is, behavioural oestrus was over). During the 1987-88 mating periods the average number of females guarded by each male was  $1.6 \pm 0.9$ , and the greatest number guarded successfully by any one male was four.

Successful guards had to repulse competitors  $4.3 \pm 1.7$  times during their female's oestrus. Although males whose takeover attempts were thwarted did not sustain observable injuries in fights, it took them  $1.3 \pm 0.5$  h ( $n = 27$ ) to locate (come within 3 m of) another oestrus female, because females were scarce and scattered (Table 1).

Nine males began guarding females, but were displaced. Seven of these were ousted during the first third of the female's period of behavioural oestrus. Subsequent guards were always heavier than the male they displaced, and there was a positive correlation between the length of guarding and male body weight ( $r = 0.79$ ,  $P < 0.01$ ). Within 20 min after a change of the guard, the new male accompanied the female underground, where they presumably copulated. Ousted males immediately resumed searching, but every receptive female approached by these males was already being guarded, and only one was successful in taking over a female. Additionally, two were carried off by hawks (one by a prairie falcon, *Falco mexicanus*, and the other by a goshawk, *Accipiter gentilis*).

The day after a female was guarded she began constructing a nest burrow and excluding all conspecifics, both males and females, from a small territory surrounding it. Females reared their litter of  $5.2 \pm 1.4$  young (range: 2-7,  $n = 59$  litters) alone, and males did not live near their mates or behave parentally.

To investigate the genetic consequences of mate guarding, I live-trapped all 26 focal females, the 20 different males that guarded them, and all 133 pups they weaned (69 in 1987, 64 in 1988). A small sample of blood ( $\sim 1$  ml) was pipetted from the suborbital sinus of each animal, separated by centrifuging, and stored in liquid nitrogen ( $-196^\circ\text{C}$ .) until analysis (8-10 weeks). Proteins were studied using standard horizontal starch-gel elec-

trophoresis and histochemical staining procedures<sup>22,23</sup>. Of 32 putative loci assayed, seven were polymorphic in blood (allele frequencies are in parentheses): adenosine deaminase (0.64, 0.36), peptidase with glycyl-leucine (0.60, 0.40), peptidase with leucyl-glycyl-glycine (0.92, 0.08), esterase A (0.84, 0.16), protein 1 (0.85, 0.14, 0.01), protein 2 (0.79, 0.21), and protein 3 (0.92, 0.08). For these allozymes, frequencies of homozygotes and heterozygotes did not differ from Hardy-Weinberg expectation (all  $P \geq 0.10$ ,  $\chi^2$  tests), and there was no evidence of linkage disequilibrium (all  $P \geq 0.20$ ,  $G$  tests) or sex-linkage.

To analyse paternity, the phenotype of every animal was determined for all seven variable loci. Then, for each litter, the phenotype of every juvenile and its dam was used to implicate or eliminate each guarding male as the sire. The results (Fig. 1b) indicate that pups born to females that had been guarded by only one male were indeed sired by that male. Litters of females guarded by more than one male were typically multiply sired (five of the seven). However, paternal representation was nonrandom: a minimum of 66-100% of pups in each of these seven litters were sired by the last/longest attending male. These results could be due either to a preponderance of sperm from the male that guarded each female longest (that is, the one that apparently mated most often) or to last male sperm precedence<sup>24,25</sup>. Preponderance is suggested by a nonsignificant but positive correlation between the number of (apparent) copulations by first guards and their maximum paternity among litters of multiply guarded females.

Male behaviour and paternity have been analysed in three other species of ground-dwelling sciurids. Black-tailed prairie dogs (*Cynomys ludovicianus*)<sup>26,27</sup> and yellow-bellied marmots (*Marmota flaviventris*)<sup>28,29</sup> are harem polygynous: an adult male lives with a group of females throughout the year and protects them from intrusions by conspecific males and predators. The resident male sires the vast majority of the young and he behaves parentally toward them. Belding's ground squirrels (*S. beldingi*), by contrast, are a lekking species: males aggregate near females' hibernacula to mate, but subsequently do not live near those females or behave parentally<sup>30-32</sup>.

In Belding's ground squirrels, receptive females were clustered (Table 1), and it took males only  $0.4 \pm 0.1$  h ( $n = 88$ ) after being defeated in a fight over a female to locate and initiate courtship with a new partner (significantly faster than male Idaho ground squirrels,  $P < 0.001$ , Mann-Whitney  $U$  test). Female *S. beldingi* typically mated with 3-5 partners, most litters were multiply sired<sup>33</sup>, and paternity varied with mating precedence: a female's first mate sired on average 0.6 of the litter, her second mate 0.3, and her third and subsequent mates 0.1 (unpublished data). Male *S. beldingi* did not guard females, but

TABLE 1 Comparison of the availability and localizability of sexually receptive females in Idaho ground squirrels and Belding's ground squirrels

Species (study site)	Year (length of mating period)	Oestrus females available per day* (range)	Distance between burrows of receptive females† (m)	Average operational sex ratio‡ (range)
<i>S. brunneus</i> (Council, Idaho)	1987 (13 days)	$1.4 \pm 1.1$ (0-4)	$128 \pm 39$ ( $N = 11$ female pairs)	1:3.2 (1:2-1:4)
	1988 (12 days)	$1.6 \pm 1.3$ (0-5)	$110 \pm 34$ ( $N = 13$ )	1:2.7 (1:2-1:4)
Significance level of comparison§		↑ ( $P < 0.01$ )	↑ ( $P < 0.001$ )	↑ NS
<i>S. beldingi</i> (Tioga Pass, California <sup>30</sup> )	1975 (16 days)	$2.6 \pm 1.2$ (1-6)	$10 \pm 3$ ( $N = 13$ )	1:3.0 (1:2-1:6)
	1976 (15 days)	$2.4 \pm 0.8$ (0-4)	$7 \pm 2$ ( $N = 9$ )	1:3.2 (1:3-1:5)
	1978 (18 days)	$2.2 \pm 1.0$ (1-5)	$9 \pm 1$ ( $N = 9$ )	1:2.4 (1:2-1:4)

Males of the Idaho ground squirrel guard their mates after copulating, whereas males of Belding's ground squirrels do not. The study areas for both species were about half a hectare.

\* Number of females that were guarded (*S. brunneus*) and mated (*S. beldingi*) on each day of the mating period.

† Nearest neighbour distances between pairs of females that were receptive on the same day.

‡ Mean daily ratio of sexually receptive females to adult males ( $\geq 2$  yr old) during the mating period.

§ Significance levels for Mann-Whitney  $U$  test comparisons between the two species (data from different years combined).

resumed mate-finding and self-advertisement as soon as copulation was complete.

Using an approach based on game theory<sup>34</sup>, I compared the effects of guarding versus searching on the fitnesses of male Idaho and Belding's ground squirrels (Table 2). These analyses suggest that mate guarding in Idaho ground squirrels is evolutionarily stable, largely because (1) locating receptive females is time-consuming for males and requires them to range widely (Table 1), which is dangerous, (2) obtaining sexual access to guarded females is difficult for all but the largest males, (3) unguarded females will mate multiply (Fig. 1a), thus diluting the first male's paternity, and (4) the longest (last) guarding male sires the majority of the litter (Fig. 1b). In contrast, conditions 1, 2, and 4 do not apply in Belding's ground squirrels and, as a result, resumption of mate searching after copulating is the evolutionarily stable state. The phenotypic costs and genetic consequences of mate guarding versus resuming searching merit investigation in other animals. □

**Note added in proof:** D. W. Foltz and P. L. Schwagmeyer have just reported<sup>35</sup> that  $75 \pm 0.8\%$  ( $n = 8$ ) of 13-lined ground squirrel

litters are sired by a female's first mate; this species thus close resembles *S. beldingi* in both male post-copulatory behavior and sperm usage pattern (Table 2).

**TABLE 2** An analysis of mate guarding behaviour versus resuming mate searching subsequent to copulating for male Idaho ground squirrels and Belding's ground squirrels, using game theory to find the evolutionarily stable state.

<i>S. brunneus</i>	<i>S. beldingi</i>
For guarding to be evolutionarily stable,	For not guarding (resuming searching) to be evolutionarily stable,
(1) $E(G, G) > E(N, G)$	$E(N, N) > E(G, N)$
Is it? If so,	Is it? If so,
(2) $[(g)(\Delta p)(l)]/t_g > [(1 - \Delta p)(l)]/t_s$	$[(1 - \Delta p)(l)]/t_s > [(g)(\Delta p)(l)]/t_g$
(3) $[(0.73)(0.83)(5.20)]/2.90 > [(0.17)(5.20)]/1.30$	$[(0.43)(4.40)]/0.40 > [(1)(0.57)(4.40)]/3.50$
(4) $1.1 > 0.7$	$4.7 > 0.7$
(units: offspring per hour)	(offspring per hour)
<b>Conclusions</b>	
Guarding is evolutionarily stable	Searching is evolutionarily stable

Schwagmeyer and Parker<sup>7</sup> adapted the 'optimal diet' model of MacArthur and Pianka<sup>36</sup> to explore the relative payoffs of mate guarding versus resuming searching by male 13-lined ground squirrels (*S. tridecemlineatus*), a species in which males do not guard. They showed that guarding a female who has just been mated (G) is evolutionarily stable against invasion by non-guarding behaviour (N) when, in a population of guarders, the expected reproductive benefits per unit time from guarding  $E(G, G)$ , exceed the expected gains per unit time from leaving the female and resuming searching  $E(N, G)$ , (inequality 1 for *S. brunneus*). Likewise, a non-guarding population (for example, *S. beldingi*) is resistant to the invasion of guarding behaviour when  $E(N, N) > E(G, N)$ . Expected gains from G and N behaviour depend on the parameters in inequality 2. For *S. brunneus*, these parameters are:  $g$ , the probability that a male can successfully guard his mate from other males, estimated as:  $19/26 = 0.73$  (assuming that overthrown males gain no further matings);  $\Delta p$ , the increase in the probability of paternity due to guarding, calculated as:  $1 - [\text{probability of paternity if the male does not guard}] = 1 - [(0.2) \times (\text{the likelihood that the abandoned female mates once more}) + 0.1 \times (\text{the likelihood that she mates twice more})] = 1 - [(0.2)(5/7) + (0.1)(2/7)] = 0.83$ ; see Fig. 1;  $l$ , the average litter size (5.2);  $t_g$ , the mean length of time a female is guarded (2.9 hours); and  $t_s$ , the mean time it takes a searching male to acquire a subsequent mate (estimated as 1.3 hours, the time it took defeated males to locate a new female). Note that both  $t_g$  and  $t_s$  are estimated conservatively relative to the inequality being examined; furthermore, predation risks, which make searching even more unfavourable, are not considered in the model. For *S. beldingi* the parameters in inequality 2 are defined similarly, but calculated differently:  $g$  is assumed to be 1.0 (that is, if males did guard females, they would do so effectively; this is the most conservative assumption relative to the inequality);  $\Delta p$  is calculated from the relative frequency of mating with 1–5 males<sup>33</sup> and the probability of paternity of the first male given that the female he leaves mates with 0–4 males subsequently (these values are  $[(0.16)(1) + (0.26)(0.6) + (0.26)(0.3) + (0.26)(0.1) + (0.06)(0)] = 0.43$ , so  $\Delta p = 0.57$ ),  $l$  is 4.4 (ref. 31);  $t_g$  is assumed to be the length of the receptive period (3.5 h; ref. 30); and  $t_s$  is 0.4 hours.

## Foraging specialization without relatedness or dominance among co-founding ant queens

**HYPOTHESES on the evolution of sociality in the Hymenoptera have focused on two non-exclusive selective processes. First, individuals may help relatives to enhance inclusive fitness (k selection<sup>1,2</sup>). Second, group living may be so highly advantageous that competitively inferior individuals are forced into subordinate roles through social competition<sup>3–7</sup>; in this hypothesis, subordinates help dominants in the expectation that they may benefit from the group's resources if the dominants lose status or die. Mai**

social Hymenoptera associate predominantly with close relatives<sup>8,9</sup>, which precludes an effective comparison of kin selection and social competition. Here we report on the existence of foraging specialists among unrelated co-foundresses of the leaf-cutter ant *Acromyrmex versicolor*; such task specialization leaves the forager at a relative fitness disadvantage within her foundress association. Contrary to the predictions of social competition theory, individuals specialize independently of competitive ability (as measured by relative body size) or reproductive status (as measured by ovarian condition) and without conflict. The selective basis of foraging specialization may lie in the intense competition that occurs among newly founded colonies engaged in reciprocal brood raiding.

In many ant species colonies are initiated by multiple foundresses<sup>10</sup>. As in other co-founding ants, *A. versicolor* foundresses do not associate preferentially by collection locale in laboratory experiments, suggesting that associations need not consist of close relatives<sup>11,12</sup>. To confirm this, we estimated within-group relatedness<sup>13,14</sup> from 26 field-caught foundress associations using allozymes as genetic markers. Of 30 tested, one locus was polymorphic<sup>14</sup>. Co-foundresses were no more closely related than randomly selected queens ( $\hat{r} = -0.12$ , s.e. = 0.03, estimated by a jack-knife over groups<sup>15</sup>). The negative  $\hat{r}$  and small s.e. imply that genotypes are distributed more evenly across groups than would be expected under random association. The negative  $\hat{r}$  is probably a sampling artefact caused by small group size ( $N = 3.8$ ) and unequal allele frequencies; we do not infer that kin avoid each other<sup>16</sup>. We conclude that associations constitute random samples of the population, precluding kin selection as an explanation for social traits<sup>17-19</sup>.

Among co-founding ants, *A. versicolor* is unique in that foundresses regularly leave the nest to forage before the emergence of the first workers. Foragers are exposed to greater risks of predation and parasitization, and to greater thermal and physical stresses than their sedentary nest-mates<sup>20-22</sup>. Nonetheless, leaves procured through foraging are shared communally in a single fungus garden. Foraging thus enhances colony fitness at the expense of a forager's relative intracolony fitness<sup>18,19</sup>. As among co-founding wasps, foraging is a task in which specialization might indicate an incipient reproductive division of labour<sup>5,23</sup>, a likely precursor to the evolution of permanent worker sterility which is characteristic of most social hymenoptera<sup>5,20,23,24</sup>.

To study the distribution of foraging effort within colonies, we established eleven colonies, each with three newly mated foundresses collected immediately after a mating flight on 23 September 1987 at North Scottsdale, Arizona. To ensure substantial size variation within each association, the mass of each foundress in an association was arranged to be at least  $\pm 1$  standard deviation (equal to 1.04 mg) from the mass of the other two foundresses. Foundresses were marked, housed in 'ant

FIG. 1 Comparative rates of foundress mortality in *A. versicolor* (squares) and the ant *Veromessor pergandei* (circles), which displays more typical behaviour for cooperatively founding ants (data for *V. pergandei* from ref. 25). Queen death rate is calculated as the percentage of all the foundresses alive at the start of a 2-day period who died during that period; it is displayed as a 3-point moving average. All observations in each nest are standardized to day of first worker emergence (day 0) in that nest. *V. pergandei* and most other cooperatively founding species reduce to secondary monogyny soon after first worker emergence<sup>28</sup>.

farms' and offered fresh native vegetation in attached foraging arenas, according to standard procedures<sup>25</sup>. Farms and associated arenas were placed on a mechanized circular surface which rotated under a video camera. Foraging trips taken by each co-foundress in each association were censused from video records of 6-hour foraging sessions (57 sessions over 14 weeks). Sessions began immediately after colony formation and ended when workers assumed foraging tasks. Farms were not offered food between sessions. In each association virtually all foraging trips (average was  $165 \pm 69$  trips per farm) were performed by a single foundress ( $P < 0.001$  in each case); the only exceptions occurred in two associations where a single secondary forager appeared after the death of the first foraging specialist.

Another 34 farms were similarly established to see if specialization in foraging was a function of potential competitive ability, as measured by relative size. These farms were spot-sampled 8 times per day for 15 weeks to estimate the number of foraging trips taken by each foundress. Chi-square analyses indicated the existence of a foraging specialist in 44 of the 45 farms in the two samples combined; the role of foraging specialist was independent of initial relative size (Table 1). At the conclusion of these experiments, all co-foundresses from 18 associations were dissected to measure primary oocyte number and size

TABLE 1 Social correlates of reproductive status among *A. versicolor* co-foundresses

	Relative initial mass*			Foraging status	
	Large	Medium	Small	Forager	Non-foragers
Forager	18	16	10		
		$(X^2 = 2.36; NS)$			
Number of primary oocytes	8.2	8.6	8.4	8.6	8.5
( $\pm$ s.d.; N)	(2.9; 18)	(1.9; 18)	(2.1; 18)	(2.2; 18)	(1.9; 35)
		$(F = 0.01; NS)$			$(t = 0.17; NS)$
Primary oocyte length, mm	0.51	0.53	0.56	0.52	0.54
( $\pm$ s.d.; N of queens)	(0.11; 16)	(0.12; 16)	(0.17; 16)	(0.10; 16)	(0.12; 32)
		$(F = 0.70; NS)$			$(t = 0.38; NS)$
Number of total oocytes	18.56	20.28	19.50	20.37	18.94
( $\pm$ s.d.; N of queens)	(13.32; 18)	(16.43; 18)	(14.56; 18)	(15.34; 19)	(14.32; 35)
		$(F = 0.06; NS)$			$(t = 0.34; NS)$

\* Each foundress in each association was  $\geq 1$  s.d. in initial mass from the other 2 foundresses in that association, such that the total number of 'large', 'medium' and 'small' foundresses was the same over all foundress associations.

(routine assays of reproductive conditions<sup>20,26,27</sup>). Reproductive condition was independent of body size and foraging specialization (Table 1); all foundresses had well developed ovaries and therefore presumably functioned as queens. During spot sampling, farms were examined for evidence of aggression that might induce a 'loser' to become a foraging specialist; in addition, the interiors of two colonies were videotaped for an average of 79 h per colony. We never saw aggression among foundresses, nor acts of ritualized dominance such as occur among some Polistine wasps<sup>5,23,27</sup> (for example, asymmetric antennation, allogrooming or trophallaxis). Access to brood or fungus, the principal resources of a colony, was never contested by, nor denied to, any co-foundress. Unlike other cooperatively founding ants<sup>25,28</sup> and some bees<sup>20</sup> and wasps<sup>29</sup>, *A. versicolor* foundresses do not fight on first worker emergence (Fig. 1), and they share resources cooperatively for at least 1.5 yr in laboratory colonies.

The primary benefit of Hymenopteran foundress associations is believed to be defence against enemies<sup>20,27,30</sup>; in some ants, the enemy is conspecific. Newly founded nests are often clumped spatially, and they engage in reciprocal brood raids; colonies with more workers (and queens to produce them) tend to prevail<sup>10,25,31</sup>. This pattern is seen clearly in *A. versicolor*, where newly founded colonies are highly clumped<sup>12</sup>, yet adult colonies are territorial<sup>32</sup>; from a group of new colonies, only a single adult colony will survive. We marked workers in 16 ant farms and paired them to common foraging areas. Brood, leaf and fungus raids occurred. Of 163 raids, 131 involved marked workers; these workers always displayed fidelity to their natal colony. Fighting among workers, and between workers and foreign queens, was common. In each pairing only a single colony survived.

As only one colony from an initial cluster of colonies will survive to adulthood, relatively small differences in colony efficiency could cause large differences in ultimate colony reproductive success. An increase in foraging efficiency should translate to a similar increase in quality of initial raiding force and, ultimately, success in eliminating rivals. Foraging social insects enhance their efficiency through experience<sup>26,33,34</sup>. An *A. versicolor* foraging queen gains experience as she gathers leaves; to refuse further foraging squanders the former resource. Yet each queen should prefer her colony mates to forage, but the simultaneous expression of such preferences would reduce colony fitness; energy and time spent in intragroup conflict over task allocation would limit the colony's future competitive potential<sup>11,35</sup>. Under these circumstances, a foundress may be relatively indifferent as to whether she is the one that suffers the mortality risk associated with foraging, because the colony will either succeed as a unit or (more probably) fail as a unit. □

## Glycine enhances NMDA-receptor mediated synaptic potentials in neocortical slices

ONE class of excitatory amino-acid receptors, the *N*-methyl-D-aspartate (NMDA) receptors, mediates transmission at a small, but important, group of synapses in the neocortex<sup>1–3</sup>. These receptors are implicated in neuronal plasticity during development in young mammals and in memory acquisition in adults<sup>4–6</sup>. Recently, responses of isolated membrane patches to NMDA were shown to be greatly enhanced by glycine<sup>7</sup>. This, together with the demonstration that the strychnine-insensitive glycine-binding site is distinct from, but linked to, the NMDA receptor<sup>8</sup> has excited intense interest in glycine as a synaptic modulator. Before proposing a physiological function, however, it is important to determine whether glycine could enhance synaptic responses to NMDA receptor activation in intact, adult tissue. An earlier study<sup>9</sup> failed to demonstrate enhancement of NMDA responses when glycine was applied and it was proposed that in intact tissue the high-affinity glycine site was already saturated by endogenous glycine. It remained possible that glycine concentrations can be maintained at low levels close to synaptic receptors. We have examined responses of neurons in slices of adult neocortex to focal applications of excitatory amino acids and glycine and report enhancement by glycine of NMDA receptor-mediated excitatory postsynaptic potentials.

So that small synaptic responses could be recorded intracellularly under controlled conditions, we used slices of adult neocortex, which does not contain any strychnine-sensitive glycine-binding sites<sup>11</sup>. The perfusing fluid was delivered at a low flow rate (less than 0.3 ml min<sup>-1</sup>) to allow metabolic products, transmitters and modulators to be controlled by natural release, degradation and uptake processes, rather than by the perfusion system.

In all cells tested in which rapid-onset, repeatable responses to electrophoretically applied excitatory amino acids could be evoked, glycine enhanced responses to NMDA (mean increase in amplitude 100.00 ± 65.75% s.d., range 22–284%, *n* = 38), but produced no significant change in responses to quisqualate (mean increase 4 ± 28.54%, range, 50% decrease to 20% increase). The effective glycine concentration is not known, but maximal effects were produced with ejection currents of less than 4 nA (Fig. 1). The responses when glycine was dissolved in acidic and alkaline solutions were similar. The effects of

glycine on NMDA responses were reversed readily when application was terminated. They were rapidly and reversibly blocked by kynurenate, an endogenous antagonist at the high-affinity glycine receptor<sup>9-10</sup>, applied electrophoretically ( $n=29$ ) or in the bathing medium ( $n=3$ ) (50–100  $\mu\text{M}$ , Fig. 1), but were unaffected by strychnine. Effective glycine currents produced no measurable change in resting potential or input resistance.

Stimulation of the white matter evoked excitatory postsynaptic potentials (e.p.s.ps) of between 1 and 5 mV. Glycine applied with a current that augmented responses to NMDA but not to quisqualate augmented the e.p.s.ps evoked in 5 of 24 of these cells (see Fig. 2a–e) and depressed the e.p.s.ps in 7 cells, without affecting the response of the cell to injected current. In a further 5 cells, larger applications of glycine (5 to 40 nA ejection current) caused decreases in both e.p.s.p. and current-pulse response (Fig. 2i, j). Glycine produced no change in the e.p.s.ps in the remaining 7 cells. Effects on e.p.s.ps were readily reversible.

All e.p.s.ps that were insensitive to, or depressed by, glycine

had conventional voltage relations and were insensitive to 2-amino-5-phosphonovaleric acid (AP5) ( $n=10/10$ ); they did not seem to contain a NMDA-receptor mediated component (Fig. 2h, k, l). In contrast, the 5 e.p.s.ps that were augmented by glycine had voltage relations that were typical of neuronal responses to NMDA<sup>1,2</sup> (Fig. 2f) and were depressed by AP5 ( $n=3/5$ ) (Fig. 2a–e). Although glycine produced a relatively small increase in the total e.p.s.p., it produced a substantial increase in the AP5-sensitive, NMDA receptor-mediated, component (Fig. 2g). Although it is possible that AP5 applied electrophoretically did not gain access to all NMDA receptors mediating the e.p.s.p., it is probable that a similar population of receptors was affected by both glycine and AP5, because we used submaximal doses of both drugs (assessed by their actions on NMDA responses) and there was no augmentation by glycine in the presence of AP5.

These results indicate that glycine can selectively enhance both neuronal responses to NMDA and NMDA-receptor-medi-

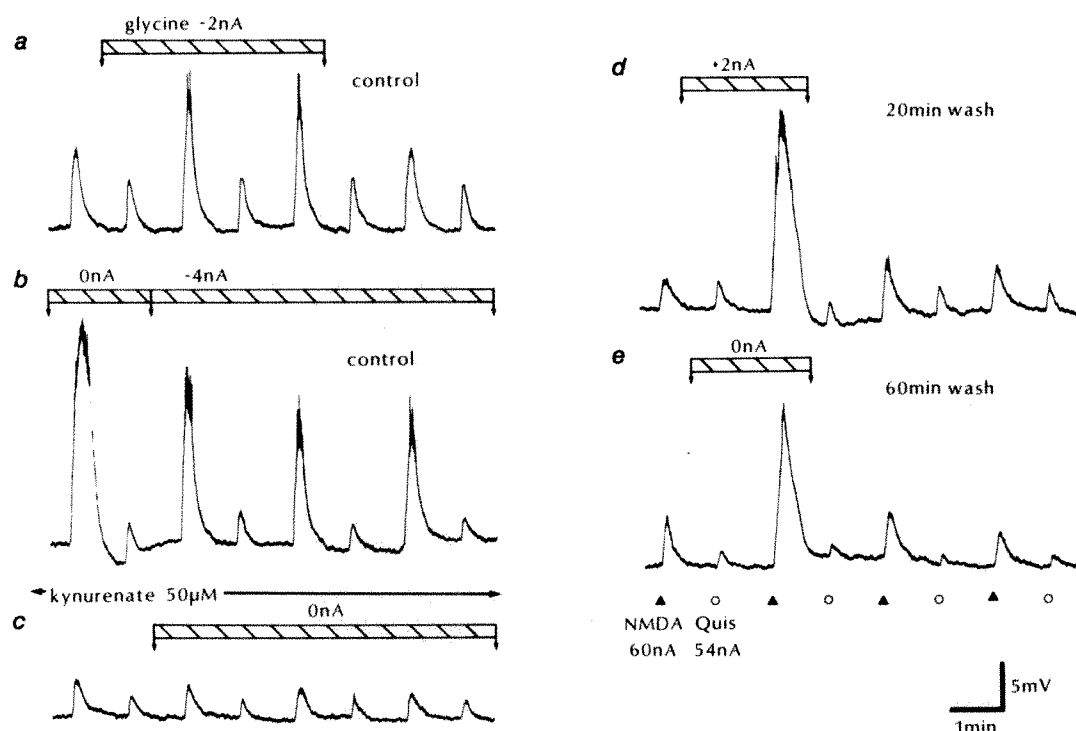

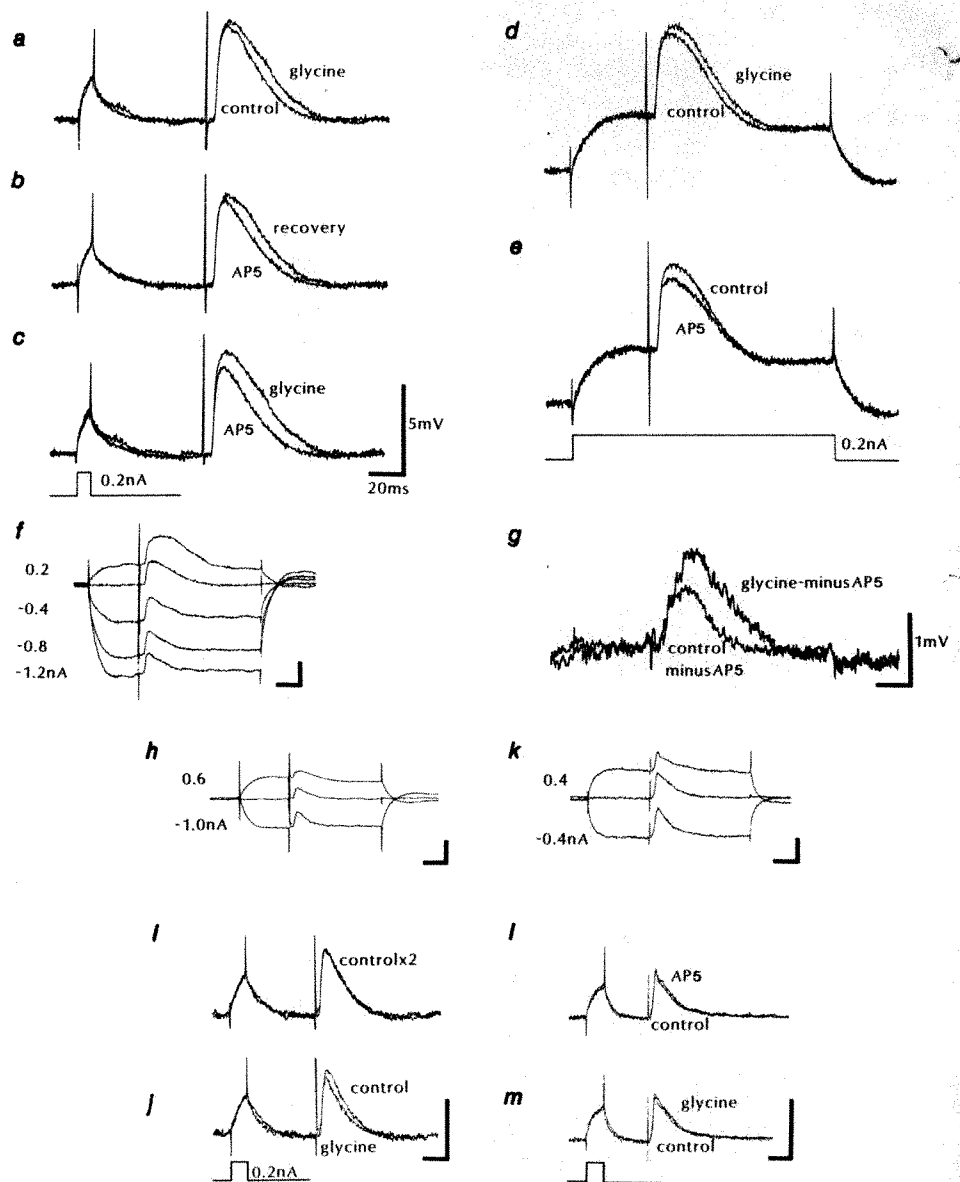

FIG. 1 Augmentation of responses to NMDA by glycine and blocking of the augmentation by kynurenate. Depolarizations of a cortical neuron in response to brief electrophoretic pulses of NMDA (closed triangles) and quisqualate (open circles), recorded intracellularly with conventional current-clamp techniques. The symbols in c and e apply to all records. Amino-acid currents were: Quisqualate, 54 nA, 2s; and NMDA, 60 nA, 2s throughout. In a, electrophoretic application of glycine (hatched bar) with a reduced retaining current (–2 nA) increased the response to NMDA, but not to quisqualate. In b, a larger application of glycine (0 nA retaining current) resulted in a larger augmentation. When the retaining current was increased to –4 nA, responses declined, but remained augmented for three further cycles until the retaining current was returned to its control value (–30 nA) when responses returned, on recovery, to pre-glycine amplitudes (data not shown). After six cycles of enhancement and recovery, kynurenate was applied in the bathing medium (50  $\mu\text{M}$ ). In c, glycine applied 25 min after kynurenate addition, with no retaining current, did not augment NMDA responses. In d, after a 20-min washout, 0 nA glycine was still ineffective (data not shown) but a +2 nA ejection current produced enhancement. In e, after a 60-min washout, 0 nA glycine caused enhancement. All records were obtained at the resting potential –72 mV ( $\pm 2$  mV). Spikes were curtailed by the pen recorder response frequency. A gradual decline in responses to both amino acids occurred

during the 3-h recording period.

**METHODS.** Coronal slices of cingulate/sensorimotor cortex were obtained from adult female Wistar (12) and male Sprague-Dawley (6) rats, as described previously<sup>2</sup>. Intracellular recordings were made from pyramidal neurons in layers II/III. Agonists and antagonists were applied electrophoretically from a 5-barrel pipette whose tip was within 50  $\mu\text{m}$  of the recording site. The barrels contained: NMDA, quisqualate (both 200 mM, pH 8), glycine (200 mM, pH 3 in 30 cells; 50 mM, pH 3 in 3 cells; 50 mM, pH 8 in 5 cells) and kynurenate (50 mM, pH 8) or D-AP5 (5 mM, pH 8) and NaCl (200 mM, balance barrel). Barrel resistances ranged from 70 to 120 M $\Omega$  in pipettes with which significant augmentation was achieved. Excitatory amino acids were applied in brief (1–2s) pulses (5–60 nA), repeated in an electronically controlled cycle with interpulse intervals of between 20 and 90 s. Glycine was applied continuously for 1 to 30 cycles either by reducing the retaining current (to 0–6 nA), or with low ejection currents (0 to 2 nA). Retaining currents for glycine of less than 10 nA resulted in a gradual loss of the augmentation of NMDA by glycine. Kynurenate ejection currents of between 2 and 20 nA rapidly and reversibly blocked the augmentation of NMDA responses by glycine. Larger currents and bath applications, of between 50 and 100  $\mu\text{M}$  reduced responses to both NMDA and quisqualate. In one experiment (three cells) strychnine (5–15  $\mu\text{M}$ ) was bath-applied.

FIG. 2 E.p.s.p.s recorded intracellularly in three cortical neurons (*a* to *g*, *h* to *j* and *k* to *m*). In *a*, the e.p.s.p. is augmented by glycine application (0 nA). After recovery (*b*), the e.p.s.p. is depressed by AP5 (10 nA). This dose of AP5 depressed responses to NMDA by more than 80%, but did not reduce quisqualate responses. The e.p.s.p.s recorded in the presence of glycine and of AP5 are superimposed in *c*; for comparison. In *a*, *b*, *c*, small injected current pulses (0.2 nA), see lower record in *c*, precede stimuli. Note the lack of effect of either AP5 or glycine on the rising phase of the e.p.s.p., which may be due to activation of non-NMDA receptors. We repeated this procedure (*d*, *e*) but with e.p.s.p.s superimposed on longer injected current pulses (0.2 nA, lower record in *e*). These responses were then digitally subtracted and amplified to reveal the AP5-sensitive component under control and glycine conditions (superimposed in *g*). *f*, The unconventional voltage relation of this e.p.s.p., which is typical of responses mediated at least in part by NMDA receptors<sup>1-3,12</sup>. Stimuli were superimposed on injected current pulses (amplitude of pulses given to the left). *h*, *k*, The conventional voltage relations of two other e.p.s.p.s. Three control averages of the e.p.s.p. shown in *h* are illustrated in *i* and in the control record *j*. This e.p.s.p. was depressed by glycine (10 nA ejection current) and there was a concurrent, if smaller, decrease in the voltage response to current injection. The e.p.s.p. shown in *k* was not significantly reduced by AP5 (*l*) nor augmented by glycine (2 nA ejection current; *m*). All records were obtained from resting potential: *a* to *g* -70 mV, *h* to *j* -72 mV, *k* to *m* -79 mV. All scale bars: 5 mV (vertical) and 20 ms (horizontal) except for *g* in which the vertical scale bar is 1 mV. *a*-*e*, *g*, *i*, *j*, *k*, *l*, *m* are averages each of 16 sweeps. *f*, *h* and *k* are averages each of eight sweeps.

**METHODS.** In six experiments, electrical stimulation ( $<1 \mu\text{A}$ ,  $<0.2 \text{ ms}$ , 1 every 5 s) of the underlying white matter was used to evoke small e.p.s.p.s. E.p.s.p.s and voltage responses to small, brief, injected current pulses were averaged (eight to 16 sweeps). Any given response was considered acceptable when three successive averages were similar in shape and amplitude. Augmentation of e.p.s.p.s by glycine, or their depression by AP5 were accepted only when responses recovered to pre-

drug levels and the effect could be repeated. For example, the e.p.s.p. illustrated in *a* to *g* was exposed to three glycine and two AP5 applications and recovered from each. Voltage relations for evoked e.p.s.p.s were obtained by superimposing e.p.s.p.s on longer duration injected current pulses.

ated e.p.s.p.s in adult neocortical slices. As the pyramidal neurons of the cortex receive many conventional, non-NMDA-receptor-mediated inputs, the contribution made by NMDA receptors to their total excitatory input is very small. Even those e.p.s.p.s that are mediated by NMDA receptors usually contain a non-NMDA-receptor-mediated component<sup>2</sup> (see also ref. 12). It is therefore unlikely that changes in local glycine concentration will dramatically change the overall excitatory drive to these cells. But because NMDA receptors are involved in neuronal plasticity, the present demonstration that NMDA-receptor-mediated responses can be enhanced by exogenous glycine indicates that glycine has an important modulatory role. □

# Regulation of NMDA receptor desensitization in mouse hippocampal neurons by glycine

Mark L. Mayer, Ladislav Vyklicky Jr & John Clements

Unit of Neurophysiology & Biophysics, Laboratory of Developmental Neurobiology, NICHD, National Institute of Health, Bethesda, Maryland 20892, USA

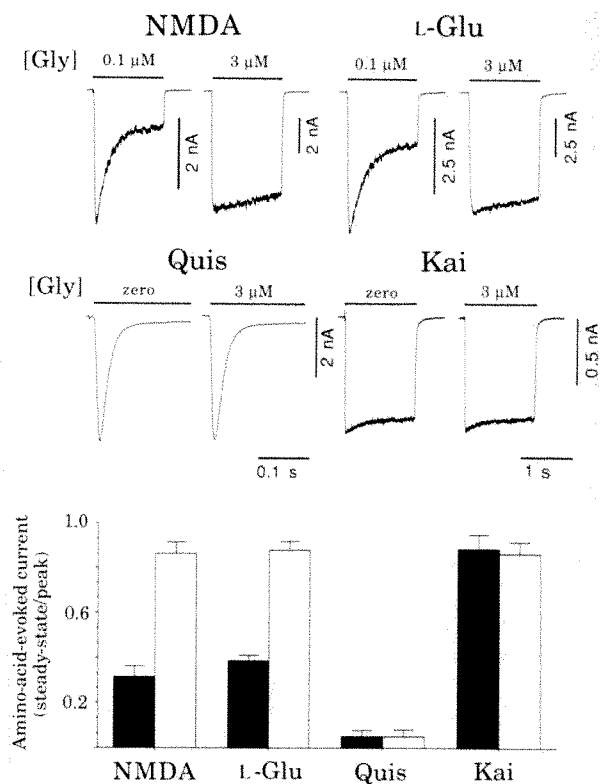

**RESPONSES** to the excitatory amino acid *N*-methyl-D-aspartate (NMDA) are markedly potentiated by nanomolar concentrations of glycine<sup>1-3</sup>. This is due to the action of glycine at a novel strychnine-resistant binding site with an anatomical distribution identical to that for NMDA receptors<sup>4,5</sup>, suggesting that the NMDA receptor channel complex contains at least two classes of amino-acid recognition site. Antagonists at the glycine-binding site associated with NMDA receptors act as potent non-competitive antagonists<sup>6,7</sup>, but do not alter the mean open time or conductance, as estimated by fluctuation analysis<sup>8</sup>. The mechanisms by which glycine acts on NMDA receptors are unknown, but single-channel recording experiments show an increase in opening frequency with no change in mean open time or conductance<sup>7</sup>, suggesting that glycine could regulate transitions to states that are intermediate

between binding of NMDA receptor agonists and ion-channel gating. It has been suggested that glycine acts as a co-agonist at the NMDA receptor, and that responses to NMDA cannot be obtained in the complete absence of glycine<sup>9</sup>, but in these experiments the response to NMDA was measured at equilibrium, and it is unlikely that sufficient temporal resolution was achieved to detect rapid alterations in receptor gating. Using a fast perfusion system we find that glycine regulates desensitization at NMDA receptors; this has a major effect on the response to NMDA measured at equilibrium, as would occur with slower applications of agonist. Reduction of NMDA receptor desensitization by glycine provides an example of a novel mechanism for regulation of ion-channel activity.

We observed that fast applications of excitatory amino acids to hippocampal neurons in dissociated culture produced three patterns of response consistent with activation of kainate, NMDA and quisqualate receptors<sup>10</sup>: responses to kainate showed little or no desensitization; responses to NMDA desensitized relatively slowly with a time constant of around 250 ms; responses to quisqualate desensitized very rapidly, with a time constant of around 10–20 ms or less. In subsequent experiments (Fig. 1) we found that desensitization at NMDA receptors, but not at kainate or quisqualate receptors, was sensitive to changes in the concentration of glycine, such that the desensitization of responses to NMDA was greatly reduced with 3 or 10  $\mu$ M glycine. Similar effects were observed with activation of NMDA receptors by both NMDA and L-glutamate, whereas D-serine and D-alanine (3  $\mu$ M) were able to substitute for glycine in preventing desensitization.

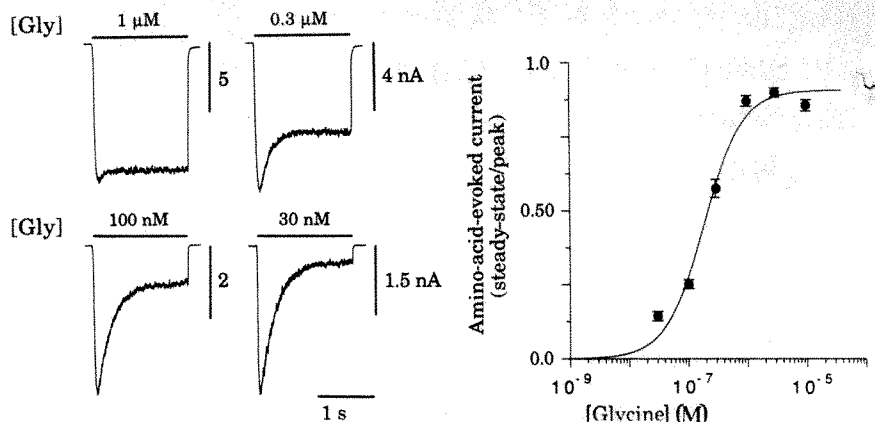

**FIG. 1** Glycine regulates desensitization at NMDA receptors, but not at kainate (Kai) or quisqualate (Quis) receptors. Responses were evoked by fast applications of NMDA (100  $\mu$ M), L-glutamate (10  $\mu$ M), quisqualate (40  $\mu$ M) and kainate (50  $\mu$ M) with 0.1  $\mu$ M and 3  $\mu$ M glycine (NMDA and L-glutamate) or zero and 3  $\mu$ M glycine (quisqualate and kainate) using whole-cell recording under discontinuous voltage clamp. The responses for NMDA and L-glutamate recorded with 0.1  $\mu$ M glycine are plotted at twice the gain of the responses recorded with 3  $\mu$ M glycine, to emphasize the effect of glycine on desensitization. The time base for responses evoked by quisqualate is 10 times faster than for the other agonists. The onset of desensitization of the responses to NMDA and L-glutamate recorded with 0.1  $\mu$ M glycine could be fitted to exponential functions of time constant 220 and 305 ms respectively. The onset of desensitization of the response to quisqualate did not change with zero or 3  $\mu$ M glycine, and could be fitted to an exponential function of time constant 17.6 ms. The responses to NMDA and L-glutamate were recorded in the same neuron, and emphasize the difference in potency of L-glutamate and NMDA, which was confirmed in separate experiments (not shown) in which complete concentration response curves were obtained for each agonist; at these doses the responses to NMDA and L-glutamate are near maximum. The residual desensitization of responses to NMDA recorded with 3  $\mu$ M glycine was fairly variable and essentially absent in some experiments; as this process was accelerated on raising the extracellular calcium concentration, or on substituting EGTA for BAPTA as an intracellular calcium buffer, we suggest that it represents a separate process, triggered by a rise in intracellular calcium ion concentration as a result of calcium influx through NMDA receptor channels. The bar graph summarizes results from experiments on nine neurons, and is plotted as steady state (measured at 1.5 s)/peak current; error bars show 1 standard deviation. Responses recorded with 0.1  $\mu$ M glycine are represented by filled columns; responses with 3  $\mu$ M glycine by open columns.

**METHODS.** Experiments used primary cultures of hippocampal neurons from 16–17-day-old mouse embryos plated on a primary culture of glial cells also from mouse hippocampus<sup>15</sup>. Neurons were kept in culture for up to three weeks, but most experiments were performed 4–14 days after plating, as development of the dendritic field made rapid solution changes more difficult to attain in older cells. In experiments in which cells were bathed in 50  $\mu$ M kainic acid and the extracellular sodium concentration stepped from 5 to 165 mM, an inward relaxation developed with a time constant of 7–10 ms indicating that there was rapid perfusion under our experimental conditions. The perfusion apparatus was similar to that used by Johnson and Ascher<sup>14,12</sup> and is described in more detail elsewhere<sup>10</sup>. The extracellular solution contained (in mM): 165 NaCl, 2.5 KCl, 2 CaCl<sub>2</sub>, 1 MgCl<sub>2</sub>, 10 glucose, 10 HEPES, pH 7.3, with 400 nM TTX (tetrodotoxin) and 5  $\mu$ M bicuculline methiodide,

and glycine added as indicated. In all experiments, neurons were pre-equilibrated with the required concentration of glycine for 10–20 s before NMDA was applied together with glycine. NMDA and L-glutamate were applied using a modified extracellular solution containing 0.2 mM CaCl<sub>2</sub> to reduce calcium-mediated inactivation of NMDA receptor activity<sup>16,17</sup> and no added Mg<sup>17,18</sup> to prevent channel block. The intracellular solution contained (in mM): 125 CsMeSO<sub>3</sub>, 15 CsCl, 5 CsBAPTA (1,2-bis(o-aminophenoxy) ethane-N,N,N',N'-tetraacetic acid), 0.5 CaCl<sub>2</sub>, 5 MgCl<sub>2</sub> and 2 ATP. Experiments were performed at room temperature (25–27 °C).

**FIG. 2** Concentration-dependent regulation by glycine of NMDA receptor desensitization. Traces show the responses to rapid applications of 100  $\mu$ M NMDA at the glycine concentrations indicated and are plotted so that the peak amplitude of the traces is similar. Desensitization is pronounced at low concentrations of glycine, but essentially absent at high concentrations of glycine. Note the similar time course of the onset of desensitization at different concentrations of glycine. Responses to 30 nM and 100 nM glycine were recorded from the same neuron, responses to 0.3  $\mu$ M and 1  $\mu$ M glycine were recorded from a second neuron. The dose-response curve summarizes results from 13 neurons each of which was tested with four concentrations of glycine. The y axis is a measure of desensitization and shows values calculated as steady-state current (measured at 1.5 s) divided by the peak-current response to NMDA. The data points are fitted by nonlinear regression to the Hill equation (maximum=0.9;  $K_d$ =185 nM;  $n$ =1.3; error bars show 1 s.d. Further analysis of these experiments showed potentiation by glycine of both the peak and steady-state response to NMDA, although because of the effect of glycine on desensitization the potentiation of the steady-state response to NMDA was much larger; on average, the peak

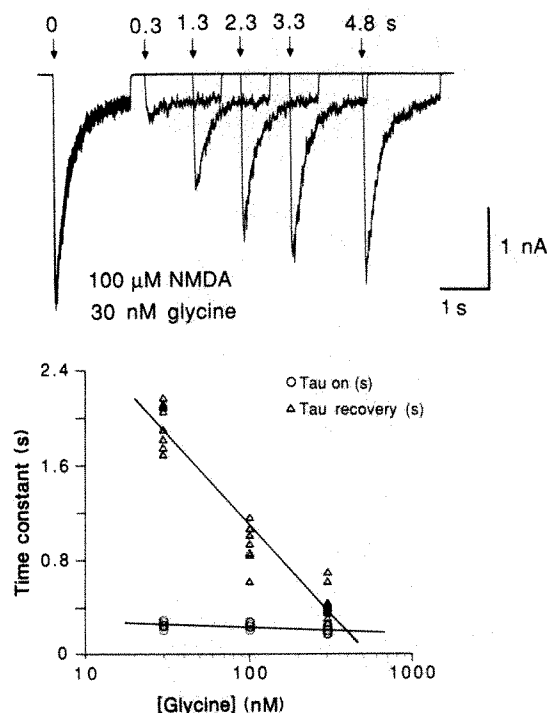

current increased by 3.53 on raising the glycine concentration from 30 nM to 10  $\mu$ M glycine, whereas the steady state current increased by 26.6. One interpretation of this result would be an agonist-evoked transition of the NMDA receptor to a state of lower affinity for glycine, such that in the presence of NMDA or L-glutamate, higher concentrations of glycine are required to maintain ion-channel activity.

Johnson and Ascher have described quantitative experiments on NMDA receptor modulation by glycine in mammalian central nervous system neurons, which suggest that glycine binds to a single site with an affinity constant of about 300 nM<sup>11</sup>; similar estimates have been obtained using binding of [<sup>3</sup>H]glycine to NMDA receptors in membrane preparations<sup>8</sup> or the application of NMDA receptor agonists to mRNA-injected oocytes under voltage clamp<sup>2,3,9</sup>. In our experiments, the potentiation by glycine of NMDA receptor responses measured at steady state (at the end of 1.5-s applications of NMDA) could be described by similar parameters: a 24-fold maximum potentiation of responses to NMDA with 10  $\mu$ M glycine compared with responses measured with 3 nM glycine, with a dissociation constant of 360 nM and  $n$ =1.3, estimated using nonlinear regression to fit the Hill equation to data recorded from 13 neurons (data not shown).

To determine whether glycine regulation of NMDA receptor desensitization occurs over a similar concentration range, we examined responses to rapid applications of NMDA in neurons pre-equilibrated for 10–20 s with 3 nM–10  $\mu$ M glycine (Fig. 2). We used this procedure to allow pre-equilibration of glycine binding, as at sub-micromolar concentrations, diffusion-limited binding of glycine would be expected to markedly slow the interaction of glycine with NMDA receptors if a rapid change in the concentration of both glycine and NMDA was made simultaneously. Our results indicate that the glycine-binding site regulating desensitization of NMDA receptors is titrated over a similar concentration range to that regulating potentiation of responses to NMDA measured at equilibrium, as the dose-response analysis of the degree of desensitization of NMDA receptor responses could be described by a binding model with a dissociation constant of 185 nM,  $n$ =1.3. The requirement that applications of agonist are fast to allow recording of desensitization at NMDA receptors is revealed by inspection of responses recorded at low glycine concentrations ( $\leq$ 100 nM) as, with 100  $\mu$ M NMDA, equilibrium desensitization (measured as the ratio of steady-state/peak current) is more than 75%, and its onset is rapid, being 90% complete within 500 ms.

Our results are in reasonable agreement with the original experiments of Johnson and Ascher<sup>1</sup> as, at the single-channel level, a reduction of desensitization by glycine would probably be recorded as an increase in frequency of ion-channel opening evoked by NMDA receptor agonists if the mean lifetime of desensitized states is long relative to the open and closed time distributions measured during normal gating behaviour of the NMDA receptor, as for nicotinic receptors<sup>12</sup>. The analysis of

**FIG. 3** Glycine increases the rate of recovery from desensitization at NMDA receptors. The traces show a family of currents evoked by paired pulse applications of 100  $\mu$ M NMDA with 30 nM glycine, recorded while the interval between the first and second pulse of NMDA was increased as indicated, to measure the speed of recovery from desensitization. In all cells studied with 30 nM glycine, complete recovery from desensitization required more than five seconds. When the peak amplitude of the response to the second application of NMDA, normalized with respect to the peak amplitude of the first response to NMDA, was plotted as a function of time, recovery from desensitization could be described by a single exponential function (tau recovery) which became faster as the concentration of glycine was increased; in the example shown, the time constant of recovery from desensitization was 3.1 s. The onset of desensitization could also be fitted by a single exponential function (tau on) but the time constant was much less sensitive to the concentration of glycine; in the traces shown, desensitization developed with a time constant of 277 ms. A graph showing the results of exponential fits to the onset and recovery from NMDA receptor desensitization in 25 experiments similar to that illustrated above is shown for 30, 100 and 300 nM glycine, and clearly shows the effect of glycine on the rate of recovery from desensitization, with minimal change in the time of onset of desensitization.

whole-cell currents provides one way to examine this possibility; we used paired pulse applications of NMDA at several concentrations of glycine to measure the rates of onset and recovery from desensitization as a function of glycine concentration (Fig. 3). Over the range 30 to 300 nM glycine, there is little change in the rate of onset of desensitization, but a dramatic speeding up of the rate of recovery from desensitization.

Although previous experiments have used fast applications of NMDA to study modulation by glycine, changes in desensitization were not reported<sup>2</sup>; this probably reflects application of agonist from a point source to a large area of membrane (*Xenopus laevis* oocytes used for voltage-clamp experiments are typically  $\geq 1$  mm in diameter), making it very difficult to achieve a rapid and uniform application of agonist, thus masking desensitization at NMDA receptors. Second, we have found that calcium influx through NMDA receptors triggers secondary mechanisms, which leads to glycine-resistant desensitization; to avoid this, we used a low extracellular concentration of calcium in all our experiments.

Further analysis of the mechanism of action of glycine on NMDA receptor channels will ultimately require a much deeper understanding of the receptor-gating process than has been achieved for any agonist-activated channel. Nonetheless, our results indicate that a major component of the action of glycine on NMDA receptors involves speeding up the rate constant of recovery from desensitization, such that NMDA receptor channels can open more frequently at equilibrium because the rate of escape from a long-lived desensitized state increases as the concentration of glycine is raised. To our knowledge, these are the first results describing regulation of ion-channel activity by an allosteric mechanism involving reduction of desensitization. Indeed, an initial inspection of the common models for desensitization at the much better characterized nicotinic acetylcholine receptor<sup>3</sup> suggests that processes that increase the degree of occupation of the agonist recognition site or the frequency of ion-channel activation would be expected to increase desensitization, as binding of agonist, receptor activation and desensitization are all tightly coupled processes. Experiments on GABA<sub>A</sub> (gamma-aminobutyric acid) receptor channels have shown that the benzodiazepine modulator chlordiazepoxide, which enhances responses to GABA, also increases the degree of desensitization at any given dose of GABA<sup>14</sup>. In contrast, modulation of desensitization at nicotinic acetylcholine receptors by substance P occurs without any change in the amplitude of the initial response to agonist<sup>20</sup> and differs from the effect of glycine described here in that it occurs by acceleration of the onset of desensitization, with no change in the rate of recovery from desensitization. As a result, substance P markedly inhibits responses to acetylcholine measured at equilibrium. Together, the effects of glycine and substance P provide dramatic examples of how modulation of desensitization can regulate the response to neurotransmitters.

Whether desensitization at NMDA receptors occurs under physiological conditions will be determined by the time course of the excitatory synaptic transmitter concentration transient at synaptic boutons. The decay time constant of the NMDA receptor component of synaptic current is unusually long and can last for hundreds of milliseconds<sup>21</sup>, which is within the period over which desensitization occurs in biophysical experiments of the type described here. The long time course for the synaptic current probably reflects the continued presence of transmitter, as we have found rapid deactivation of NMDA receptor current (time constant  $\leq 10$  ms) on removal of agonist in concentration jump experiments. This suggests that the regulation by glycine of NMDA receptor desensitization *in vivo* could have important functional consequences. □

## Cytosolic calcium regulates ion channels in the plasma membrane of *Vicia faba* guard cells

Julian I. Schroeder & Susumu Hagiwara

Department of Physiology, Jerry Lewis Neuromuscular Research Center, UCLA School of Medicine, Los Angeles, California 90024, USA

THE molecular mechanisms by which  $\text{Ca}^{2+}$  controls a variety of ion transport-associated cellular functions in higher plant cells<sup>1</sup>, including movements of stomatal pores, remain unknown. Stomatal pores regulate the gas exchange in leaves. Openings of stomatal pores are mediated by an increase in the intracellular potassium and anion content of guard cells<sup>2,3</sup>. Voltage-dependent  $\text{K}^+$  channels<sup>4–7</sup> and hyperpolarizing  $\text{H}^+$  pumps<sup>8,9</sup> have been identified as mechanisms controlling stomatal movements. But depolarizing mechanisms required for  $\text{K}^+$  efflux during stomatal closing remain unknown. Indirect evidence suggests that  $\text{Ca}^{2+}$  triggers stomatal closing and inhibits stomatal opening<sup>10–12</sup>. Using patch-clamp techniques<sup>13</sup>, we show here that elevated (micromolar) concentrations of cytosolic  $\text{Ca}^{2+}$  in guard cells block inward rectifying  $\text{K}^+$  channels. Furthermore, elevation of cytosolic  $\text{Ca}^{2+}$  leads to the activation of a voltage-dependent depolarizing conductance with a permeability to anions. The  $\text{Ca}^{2+}$ -induced modulation of ion channels reported here could provide a molecular basis for  $\text{Ca}^{2+}$ -dependent regulation of stomatal movements in leaves.

Figure 1a illustrates typical voltage-dependent inward and outward conducting  $\text{K}^+$  channel currents<sup>5,6</sup> recorded across the plasma membrane (plasmalemma) of a guard cell using the whole-cell patch clamp technique<sup>13</sup>. When the cytoplasmic  $\text{Ca}^{2+}$  concentration ( $[\text{Ca}^{2+}]_{\text{cyt}}$ ) was buffered to low values of 0.01  $\mu\text{M}$  and 0.1  $\mu\text{M}$ , the inward conducting  $\text{K}^+$  current ( $I_{\text{K}^+, \text{in}}$ ) was activated at potentials more negative than  $-87$  mV ( $\pm 12$  mV,  $\pm$  s.e.m.  $n = 12$ ) (Fig. 1a and c).

Raising the cytosolic  $\text{Ca}^{2+}$  concentration to 1.5  $\mu\text{M}$  resulted in several dramatic changes in the guard cell membrane currents (Fig. 1b). The inward rectifying  $\text{K}^+$  current was inhibited in the normal activation range when  $[\text{Ca}^{2+}]_{\text{cyt}}$  was elevated (Fig. 1b, c). With 1.5  $\mu\text{M}$   $[\text{Ca}^{2+}]_{\text{cyt}}$ , time-dependent inward rectifying currents were activated at potentials more negative than  $-192$  mV ( $\pm 13$  mV,  $\pm$  s.e.m.,  $n = 19$ ) (Fig. 1b). When  $[\text{Ca}^{2+}]_{\text{cyt}}$  was buffered to 9  $\mu\text{M}$ , inward current activation occurred at potentials more negative than  $-196$  mV ( $\pm 13$  mV,  $n = 11$ ). Tail currents<sup>5</sup> of these hyperpolarization-induced currents at elevated  $[\text{Ca}^{2+}]_{\text{cyt}}$  reversed at the  $\text{K}^+$  equilibrium potential, indicating that they

were carried by  $K^+$  ions (data not shown). Thus, elevation of cytosolic  $Ca^{2+}$  seems to shift the activation potential of  $I_{K^+,in}$  to large negative potentials.

To test this suggestion, single-channel currents were recorded in cell-free outside-out membrane patches<sup>13</sup> (Fig. 2). With low free  $Ca^{2+}$  concentrations ( $0.01 \mu M$ ) on the cytoplasmic side of the membrane, increasingly negative potentials enhanced the probability of channel opening (Fig. 2a). But when  $[Ca^{2+}]_{cyt}$  was elevated, only few discrete single-channel current steps were observed at large negative potentials (Fig. 2b).

Single-channel conductances recorded at low cytoplasmic  $Ca^{2+}$  ranged from 5 to 8 pS ( $10^{-12} \Omega^{-1}$ ,  $n = 3$ ). Channel conductances recorded at elevated  $[Ca^{2+}]_{cyt}$  were 4–7 pS ( $n = 3$ ). Extrapolation of single-channel current amplitudes with low and elevated  $[Ca^{2+}]_{cyt}$  resulted in reversal potentials close to the  $K^+$ -equilibrium potential ( $E_{K^+} = -54$  mV). These results indicate that the  $Ca^{2+}$ -dependent reduction of  $I_{K^+,in}$  was mediated by a shift in the activation potential of  $I_{K^+,in}$  channels to large negative potentials. Moreover, experiments with excised membrane patches demonstrate that cytoplasmic  $Ca^{2+}$  modulates  $I_{K^+,in}$  channels by directly effecting plasma membrane-bound processes, rather than by interacting with other intracellular factors.

FIG. 1 Effect of cytosolic  $Ca^{2+}$  on guard cell plasma membrane currents in whole-cell recordings. **a**, Inward conducting  $K^+$  currents<sup>4–6</sup> (downward deflections) and outward conducting  $K^+$  currents<sup>5–7</sup> (upward deflections) recorded with  $0.1 \mu M$  free cytosolic  $Ca^{2+}$ . Consecutive one-second voltage steps were applied from a holding potential of  $-75$  mV to pulse potentials ( $V_{Pulse}$ , between the arrows) ranging from  $+61$  mV to  $-170$  mV, as indicated to the right of currents. After  $V_{Pulse}$ , the membrane was stepped to  $-115$  mV ( $V_{Tail}$ ). (The group of rapidly deactivating currents at  $V_{Tail} = -115$  mV corresponded to deactivation of  $I_{K^+,out}$ , whereas the group of slowly deactivating currents corresponded to deactivation of  $I_{K^+,in}$ .) Whole-cell capacitance was  $5.35$  pF. Membrane potential was  $-52$  mV (zero current). **b**, Whole-cell currents measured as described in **a**, with  $1.5 \mu M$  free  $Ca^{2+}$  in the cytoplasm. The membrane potential was  $-20$  mV (zero current). The zero-current level is indicated by the broken line on the right in **(a)** and **(b)**. Whole-cell capacitance was  $5.57$  pF. **c**, Normalized whole-cell currents from cells shown in **(a)** and **(b)** plotted as a function of  $V_{Pulse}$  (open circles:  $[Ca^{2+}]_{cyt} = 0.1 \mu M$ ; crosses:  $[Ca^{2+}]_{cyt} = 1.5 \mu M$ ).

**METHODS.** Guard cell protoplasts were isolated from the lower leaf epidermis of *Vicia faba* as previously described<sup>6</sup> and were bathed during recordings in external solution containing:  $10$  mM potassium glutamate,  $2$  mM  $MgCl_2$ ,  $1$  mM  $CaCl_2$ ,  $1$  mM KOH,  $10$  mM MES 2-[*N*-morpholino]ethanesulphonic acid, pH 5.5, osmolality adjusted to  $480$  mmol  $kg^{-1}$  with D-mannitol. The internal solution, which equilibrated with the cytoplasm, contained:  $100$  mM potassium glutamate,  $2$  mM  $MgCl_2$ ,  $4$  mM KOH,  $10$  mM HEPES,  $4$  mM MgATP, pH 7.2, and D-mannitol, osmolality  $530$  mmol  $kg^{-1}$ . Concentrations of free  $Ca^{2+}$  were buffered in the internal solution by addition of  $0.45$  mM  $CaCl_2$  and  $1.1$  mM  $K_2$ -EGTA in **(a)** and by addition of  $1$  mM  $CaCl_2$  and  $2$  mM 5,5'-dibromobAPTA, tetrapotassium ( $K_4$ -D-Br-BAPTA) (Molecular Probes, Oregon) in **(b)**.  $Ca^{2+}$ -EGTA buffers (dissociation constant  $K_D = 0.147 \mu M$ ) were prepared to compensate for impurities of EGTA<sup>30</sup>.  $Ca^{2+}$  buffers using  $K_4$ -D-Br-BAPTA ( $K_D \sim 1.5 \mu M$ )<sup>30</sup> were corrected for impurities and effects of ionic strength by calibration of internal solutions using  $Ca^{2+}$ -selective electrodes. Voltage-clamp and zero current-clamp recordings were performed with an EPC-7 patch-clamp amplifier (List Electronic) and analysed<sup>6</sup> on a PDP 11/23 computer. The membrane was voltage-clamped to  $-75$  mV for 12 s between consecutive voltage pulses. Liquid junction and series resistance potentials were accounted for<sup>6</sup>. All whole-cell recordings had effective access resistances<sup>5</sup> of  $\leq 10$  M $\Omega$  to ensure efficient control of  $[Ca^{2+}]_{cyt}$ . The temperature was  $22^\circ C$ .

Elevation of  $[Ca^{2+}]_{cyt}$  produced further changes in the ionic currents of guard cells. Depolarizing voltage steps with  $1.5 \mu M$   $[Ca^{2+}]_{cyt}$  enhanced voltage-dependent instantaneous currents (Fig. 1b) in addition to the time-dependent  $K^+$  currents observed at low  $[Ca^{2+}]_{cyt}$ , and repolarization of the membrane to  $-115$  mV ( $V_{Tail}$ ) evoked slow relaxation currents in addition to the rapidly deactivating  $I_{K^+,out}$  tail currents (compare  $V_{Tail} = -115$  mV in Fig. 1a, b). In current-clamp recordings of whole cells dialysed with low  $[Ca^{2+}]_{cyt}$  ( $\leq 0.1 \mu M$ ), the membrane potentials ( $V_m$ ) were never more positive than the activation potential of  $I_{K^+,out}$  ( $V_m = -39 \pm 15$  mV,  $\pm$ s.e.m.,  $n = 11$ ). Interestingly, elevation of cytosolic  $Ca^{2+}$  levels ( $1.5 \mu M$  and  $9 \mu M$ ) often resulted in membrane potentials that were more positive than the activation potential of whole-cell currents (Fig. 1b, c).

To examine the ion selectivity of the  $[Ca^{2+}]_{cyt}$ -dependent depolarizing currents, solutions were prepared that would shift anion equilibrium potentials to more positive values and cation equilibrium potentials to more negative values (see Fig. 3 legend). Furthermore, to abolish  $K^+$  channel currents, we replaced  $K^+$  in the cytoplasmic and bath solutions by minutely permeant  $Cs^+$  ions<sup>6</sup>. With  $0.01 \mu M$   $[Ca^{2+}]_{cyt}$  in whole cells, only small currents were recorded (Fig. 3a), whereas  $Ca^{2+}$ -activated currents appeared with  $1.5 \mu M$   $[Ca^{2+}]_{cyt}$  (Fig. 3b).

Using these  $\text{Cs}^+$  solutions, the membrane potentials ( $V_m$ ) of the cells with elevated  $[\text{Ca}^{2+}]_{\text{cyt}}$  ( $1.5 \mu\text{M}$ ) depolarized to  $+15 \text{ mV}$  ( $\pm 12 \text{ mV}$ ,  $\pm \text{s.e.m.}$ ,  $n = 7$ ). When  $\text{Cs}^+$  ions were replaced by  $\text{K}^+$  ions in the solutions used in Fig. 3, membrane potentials also depolarized with  $1.5 \mu\text{M}$   $[\text{Ca}^{2+}]_{\text{cyt}}$  ( $V_m = +9 \pm 8 \text{ mV}$ ,  $\pm \text{s.e.m.}$ ,  $n = 9$ ). But membrane potentials were substantially more negative when cytosolic  $\text{Ca}^{2+}$  was buffered to low concentrations of  $0.01$  and  $0.1 \mu\text{M}$  ( $V_m = -40.5 \pm 15 \text{ mV}$ ,  $\pm \text{s.e.m.}$ ,  $n = 15$ ).

Although  $[\text{Ca}^{2+}]_{\text{cyt}}$  may also modulate outward  $\text{K}^+$  currents, the  $\text{Ca}^{2+}$ -activated depolarizing currents can be attributed only to  $\text{Ca}^{2+}$  or anion permeation, as the equilibrium potentials of all other ions present were  $0 \text{ mV}$ , or more negative (Fig. 3 legend). Lowering external  $\text{Ca}^{2+}$  from  $1 \text{ mM}$  to  $0.1 \text{ mM}$  did not hyperpolarize the membrane or reduce currents, as seen in Fig. 3b. These results indicate that the  $\text{Ca}^{2+}$ -activated depolarizing currents were not carried by  $\text{Ca}^{2+}$  ions and suggest that membrane depolarizations were induced by a  $\text{Ca}^{2+}$ -activated anion permeability. This suggestion was supported by the finding that the membrane depolarized to between  $+30 \text{ mV}$  and  $+50 \text{ mV}$  when the cytoplasm was loaded with solutions containing  $100 \text{ mM}$   $\text{CsCl}$  and cells were bathed in  $10 \text{ mM}$   $\text{CsCl}$  ( $n = 4$ ).

The  $\text{Ca}^{2+}$ -activated currents and the  $\text{Ca}^{2+}$ -induced depolarizations usually diminished within 2–10 min of establishing whole-cell recordings ('wash-out'). The 'wash-out' of the  $\text{Ca}^{2+}$ -dependent depolarizing currents indicated that other factors may be important for the activation of this conductance.

Our results directly demonstrate that variation of cytosolic  $\text{Ca}^{2+}$  in the range reported to be physiological ( $0.1$  to  $10 \mu\text{M}$ )<sup>14–19</sup>, strongly modulates ion channels in the plasma membrane of a higher plant cell. Extracellular manipulations of  $\text{Ca}^{2+}$  in stomata during physiological stimulation by light and abscisic acid<sup>10–12</sup> have recently indicated that  $\text{Ca}^{2+}$  may exert two separate actions on stomatal movements: first,  $\text{Ca}^{2+}$  is required to initiate stomatal closing<sup>10–12</sup> which relies on reduction of the  $\text{K}^+$  and anion content of guard cells<sup>2,20</sup>; and second,  $\text{Ca}^{2+}$  inhibits stomatal opening<sup>10–12</sup> and the required  $\text{K}^+$  influx<sup>11</sup>.

Previous investigations have provided biophysical and pharmacological evidence that  $I_{\text{K}^+, \text{in}}$  channels represent a major pathway for  $\text{K}^+$  influx during stomatal opening<sup>4–6</sup>. Thus, the inhibition of  $I_{\text{K}^+, \text{in}}$  channels at elevated  $[\text{Ca}^{2+}]_{\text{cyt}}$  reported here may provide a mechanism for the observed prevention of stomatal opening by  $\text{Ca}^{2+}$ . In animal cells, elevation of  $[\text{Ca}^{2+}]_{\text{cyt}}$  can activate outward conducting  $\text{K}^+$  channels<sup>21,22</sup>. Interestingly, both the  $[\text{Ca}^{2+}]_{\text{cyt}}$ -dependent inhibition of  $I_{\text{K}^+, \text{in}}$  found here, and  $\text{Ca}^{2+}$  stimulation of  $\text{K}^+$  channels in animal cells are mediated by hyperpolarizing shifts in the activation potential at increased  $[\text{Ca}^{2+}]_{\text{ext}}$  (Figs 1 and 2; ref. 22).

In addition to reducing  $I_{\text{K}^+, \text{in}}$ , elevation of  $[\text{Ca}^{2+}]_{\text{cyt}}$  led to activation of a voltage-dependent depolarizing conductance

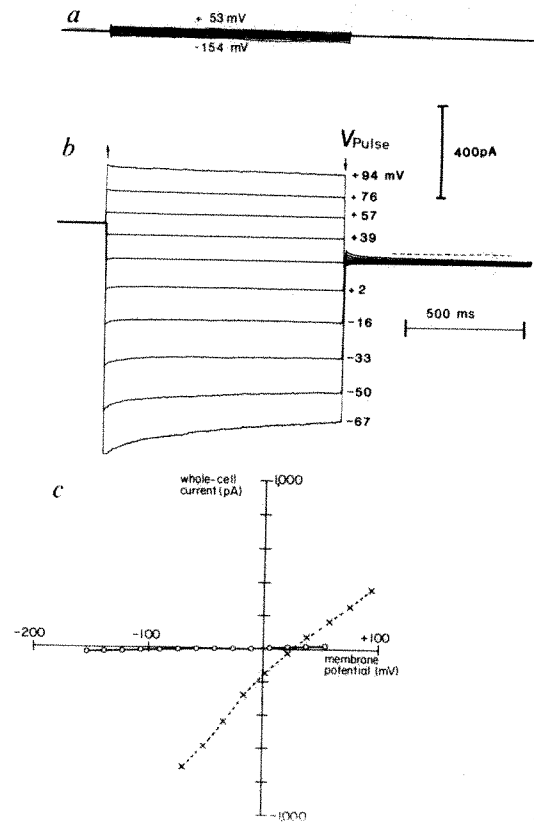

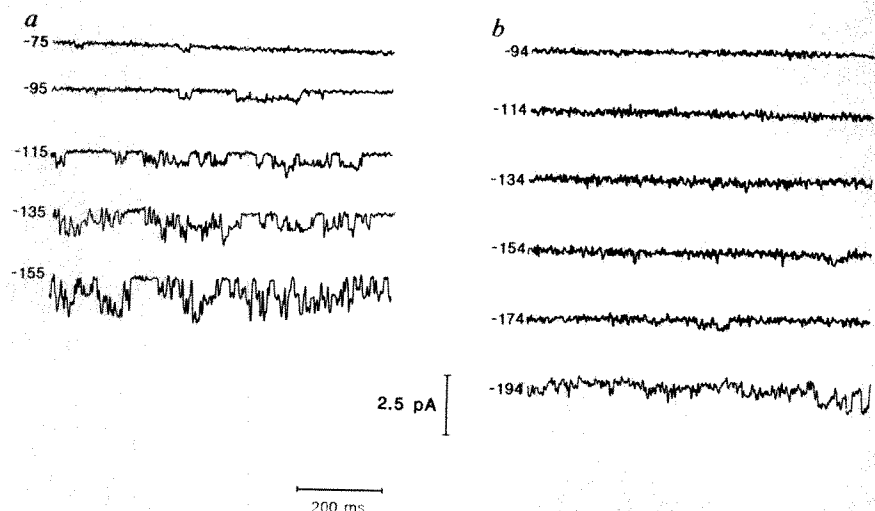

FIG. 3 Effect of cytosolic  $\text{Ca}^{2+}$  on whole-cell currents recorded with  $\text{Cs}^+$  solutions. **a**, Whole-cell currents in response to voltage steps in the range from  $+53 \text{ mV}$  to  $-154 \text{ mV}$  with the cytoplasm exposed to  $0.01 \mu\text{M}$   $\text{Ca}^{2+}$ . **b**, Whole-cell currents in response to voltage steps from  $+48 \text{ mV}$  with  $1.5 \mu\text{M}$  free  $\text{Ca}^{2+}$  in the pipette solution. The zero-current level is indicated by the broken line on the right. In 84% of the guard cell protoplast preparations ( $n = 25$ )  $\text{Ca}^{2+}$ -activated currents as shown in Figs 1b and 3b were detected ('wash-out'). **c**, Current-voltage relationships of cells shown in (a) and (b) (open circles:  $[\text{Ca}^{2+}]_{\text{cyt}} = 0.01 \mu\text{M}$ ; crosses:  $[\text{Ca}^{2+}]_{\text{cyt}} = 1.5 \mu\text{M}$ ). The internal  $\text{Cs}^+$  solution contained:  $80 \text{ mM}$   $\text{Cs}_2\text{-EGTA}$  in (a) and  $1 \text{ mM}$   $\text{CaCl}_2$ ,  $2 \text{ mM}$   $\text{K}_4\text{-D-Br-BAPTA}$  in (b). The external  $\text{Cs}^+$  solution contained:  $8 \text{ mM}$   $\text{Cs-glutamate}$ ,  $0.5 \text{ mM}$   $\text{CsCl}$ ,  $1 \text{ mM}$   $\text{CaCl}_2$ ,  $10 \text{ mM}$   $\text{HEPES}$ ,  $\text{pH } 7.2$ , with osmolalities as in Fig. 1. Using these solutions, the  $\text{Cl}^-$  equilibrium potential ( $E_{\text{Cl}^-}$ ), after correction for ionic activities<sup>6</sup>, was shifted from  $0 \text{ mV}$ , as was the case for solutions used in Fig. 1b, to  $+54 \text{ mV}$  in Fig. 3b ( $E_{\text{glutamate}} = +54 \text{ mV}$ ;  $E_{\text{Ca}^{2+}} > +82 \text{ mV}$ ), whereas  $E_{\text{H}^+}$  was shifted from  $+100 \text{ mV}$  to  $0 \text{ mV}$  and the equilibrium potential for free divalent cations was shifted from  $+5 \text{ mV}$  to  $-9 \text{ mV}$  (compare solutions in Figs 1 and 3).

FIG. 2 Cytosolic  $\text{Ca}^{2+}$  modulates single  $I_{\text{K}^+, \text{in}}$  channels in outside-out plasma membrane patches. The membrane potential of outside-out patches was continuously polarized to negative values at which the time-dependent activation of single  $I_{\text{K}^+, \text{in}}$  channels has previously been described<sup>5</sup>. **a**, Recordings of single  $\text{K}^+$  channel currents at  $0.01 \mu\text{M}$   $[\text{Ca}^{2+}]_{\text{cyt}}$ . Increasingly negative holding potentials, as indicated to the left of the current traces, led to increased opening of  $I_{\text{K}^+, \text{in}}$  channels. Small patch pipette tips were used to reduce the number of channels in the patch (tip resistance  $10 \text{ M}\Omega$  in  $150 \text{ mM}$   $\text{KCl}$  solutions<sup>4</sup>). **b**, Current recordings in an outside-out membrane patch with  $9 \mu\text{M}$  free  $\text{Ca}^{2+}$  on the cytoplasmic membrane side. Cytosolic  $\text{Ca}^{2+}$  was buffered to  $9 \mu\text{M}$  by addition of  $0.66 \text{ mM}$   $\text{CaCl}_2$  and  $0.77 \text{ mM}$   $\text{K}_4\text{-D-Br-BAPTA}$ . Solutions are described in the legend to Fig. 1.

with a permeability to anions. As mature guard cells are uncoupled from neighbouring epidermal cells<sup>23</sup>, the observed  $[Ca^{2+}]_{\text{cyt}}$ -induced depolarizations to about +10 mV may take place in guard cells embedded in their natural environment. Such depolarizations have been estimated to be sufficient to drive physiological rates of  $K^+$  efflux through  $I_{K^+, \text{out}}$  channels<sup>4,5</sup>.  $Ca^{2+}$  can therefore trigger release of both  $K^+$  and anions<sup>20</sup>, providing a mechanism for the  $Ca^{2+}$  requisite for closure of stomatal pores<sup>10-12</sup>.

The close correlations between  $[Ca^{2+}]_{\text{cyt}}$ -dependent ion channels and the effects of  $Ca^{2+}$  on stomata suggest that the  $Ca^{2+}$ -dependent mechanisms reported here may provide a molecular basis for the regulation of ion transport during stomatal opening and closing.  $I_{K^+, \text{out}}$  channels<sup>24-27</sup> and, more recently,  $I_{K^+, \text{in}}$  channels<sup>27</sup> with similar properties to those described in guard cells, have been characterized in other higher plant cells (for review, see refs 28, 29). Studies of effects of cytosolic  $Ca^{2+}$  on ion channels in these cells may increase our general understanding of  $Ca^{2+}$ -dependent osmoregulation in higher plant cells. □

## Separate lineages of T cells expressing the $\alpha\beta$ and $\gamma\delta$ receptors

Astar Winoto & David Baltimore

Whitehead Institute for Biomedical Research, 9 Cambridge Center, Cambridge, Massachusetts 02142, USA, and Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

THE T-cell antigen receptor is a heterodimer molecule composed of either  $\alpha\beta$  or  $\gamma\delta$  chains. The  $\alpha\beta$  receptor molecules are expressed mainly in  $CD4^+ CD8^-$  and  $CD4^- CD8^+$  T cells (helper and killer T cells respectively), whereas the  $\gamma\delta$  receptor molecules are expressed mainly in  $CD4^- CD8^-$  T cells<sup>1-3</sup>.  $CD4^+ CD8^-$  and  $CD4^- CD8^+$  T cells arise from a class of  $CD4^- CD8^-$  T cells during thymus development<sup>4</sup>, raising the question of whether cells

rearranging their  $\gamma\delta$  receptors later give rise to  $\alpha\beta$  T cells further rearrangements of their receptor genes, or whether rearrangements and expression of the receptor genes occur in separate lineages. The  $\delta$ -chain gene is located between the  $V\alpha$  (variable) and  $J\alpha$  (joining) gene segments<sup>5,6</sup> and when the rearrangement allowing  $\alpha$ - and  $\beta$ -receptors occur, the DNA between these segments is deleted as small circles which can be isolated from developing thymocytes<sup>7,8</sup>. The rearrangement status of the  $\delta$ -chain gene in the  $\alpha$ -circles can therefore be investigated to see whether  $\alpha$ -chain and  $\delta$ -chain expression occur in parallel lineages sequentially within a lineage. We find that the  $\delta$ -chain gene in the T-cell receptor  $\alpha$ -circles has a germline configuration, indicating that  $\alpha\beta$  and  $\gamma\delta$  T cells are distinct lineages.

To analyse the  $\delta$ -chain gene rearrangement status in  $\alpha$ -producing T cells, two independent circle libraries were made from the thymuses of AKR mice. The circular DNA isolate was extensively purified (see legend to Table 1), cut with *Eco*RI and cloned into the  $\lambda$  vectors. We obtained  $5 \times 10^4$  recombinant and  $5 \times 10^3$  clones for the first and the second libraries respectively.

TABLE 1 Number of clones from circle libraries that hybridized to specific probes

Probes	Library 1	Library 2
<i>Ja</i> 26	0	0
<i>Ja</i> 27	>300	>100
<i>Ja</i> 19	55	ND
<i>Ja</i> 57	45	ND
A	>500	ND
B	>500	48
C	>500	46
A <sup>+</sup> B <sup>+</sup> C <sup>+</sup>	>500	—
B <sup>+</sup> C <sup>+</sup>	—	46
A <sup>+</sup> C <sup>+</sup>	2	ND
B <sup>+</sup> C <sup>+</sup>	ND	2

Several *Ja* oligonucleotides (*Ja*19, *Ja*57, *Ja*26 and *Ja*27)<sup>9</sup> were used as probes and hybridized to the circle libraries. The *Ja*26 gene segment the most  $\alpha$ -proximal, located 3 kb 5' of *Ca*. The *Ja*19 and *Ja*57 gene segments are located on one *Eco*RI fragment at 41 kb and 38 kb 5' of *C* respectively. The *Ja*27 gene segment is located 60 kb from *Ca* (ref. 9). The oligonucleotide sequences are: *Ja*19, ACCAGCTGAAGGTTA; *Ja*57, AACTTTACAAGTGCAAC; *Ja*26, ACCCAAGTGACGGTAAT; *Ja*2 GCTGACAGTGAGCTCAT. Prehybridization was at 65 °C for 5 h in  $6 \times$  SS 5 × Denhardt's solution, 0.1% SDS and 250  $\mu$ g ml<sup>-1</sup> of denatured salmon sperm DNA. Hybridization was at 37 °C overnight in the above-mentioned buffer containing oligonucleotide probe. Washing was at 37 °C for 2 h with several changes. Circle libraries were prepared essentially as described Okazaki *et al.*<sup>8</sup> Briefly, thymuses from 50 4-5-week-old mice were taken and washed in PBS buffer. The thymocytes were then resuspended in 20 ml nuclear homogenization buffer (0.3 M sucrose, 20 mM Tris-HCl, pH 7.6, 10 mM KCl, 0.5 mM EDTA, 3 mM CaCl<sub>2</sub>) and homogenized with a type B pestle in Dounce homogenizer for <10 strokes. NP40 was added to a final concentration of 0.5% and cells were homogenized again for 7 strokes, or until nuclear breakage was complete. The nuclei were then collected by centrifugation at 2,000 r.p.m. for 5 min and washed 3 times with the same homogenization buffer (30 ml) and 0.5% NP40. The final nuclear pellet was resuspended in 20 ml homogenization buffer, to which 800  $\mu$ l 0.5 M EDTA, 400  $\mu$ l Triton X-100 and 400  $\mu$ l 20% Sarkosyl were added, and the mixture incubated for an additional 15 min on ice. The supernatant obtained after 30 min centrifugation in the SW41 rotor at 40,000 r.p.m. was poured off carefully and phenol-extracted. After extensive dialysis against 10 mM Tris-HCl, pH 7.6, 1 mM EDTA and 100 mM NaCl, the resulting material was banded in a CsCl/ethidium bromide gradient in the presence of 50  $\mu$ g intact pUCPv plasmid DNA as a carrier (pUCPvull is pUC18 plasmid with the small *Pvu*II fragment removed, hence the plasmid does not contain any polylinker sequences and cannot be cloned in an *Eco*RI-cloning vector). Supercoiled DNA was collected and banded one more time. The supercoiled DNA was then extracted with butanol and ethanol-precipitated. Any residual linear DNA was digested with an ATP-dependent DNase I, leaving the supercoiled DNA intact. For cloning, the final preparation of DNA was cut with *Eco*RI and packaged into a  $\lambda$ gt7 vector or  $\lambda$ Zap vector (Stratagene).

ND, Not determined.

To show that the libraries consisted mainly of clones from circular DNA molecules, four  $J\alpha$  oligonucleotide probes specific for the non-conserved portion of the  $J\alpha$  gene and located at different distances from  $C\alpha$  (constant) were used in a hybridization analysis. If the library derived from circles formed during proper rearrangements, the most  $C\alpha$ -proximal  $J\alpha$  segment should be absent from the library, and representation should ideally increase with 5' distance from  $C\alpha$ . As predicted, the probe for the most  $C\alpha$ -proximal gene segment,  $J\alpha 26$  (ref. 9), did not hybridize to any library clone (Table 1). By contrast, the  $J\alpha 27$  oligonucleotide hybridized to several hundred clones in both libraries. Indeed, the unusually high frequency of  $J\alpha 27$ -positive clones indicated that we had cloned circular DNA containing an over-representation of the T cell receptor  $J\alpha$  region. Because we used *EcoRI* as the restriction enzyme to cut the circular DNA during the cloning process, hybridization with the probes for the regions  $J\alpha 19$  and  $J\alpha 57$  located within a single *EcoRI* restriction fragment was particularly informative in assessing the status of the libraries. In the first circle library, 55 clones hybridized to the  $J\alpha 19$  probe, whereas 45 hybridized to  $J\alpha 57$  (Table 1). All 45  $J\alpha 57^+$  clones were also  $J\alpha 19^+$ , indicating that they contained the *EcoRI* fragment of the  $\alpha$ -chain circle in the germline configuration. Because the  $J\alpha 19$  gene segment is located 5' to the  $J\alpha 57$  gene segment, the rest of the  $J\alpha 19^+$  clones, which were  $J\alpha 57^-$ , presumably contained the  $\alpha$ -chain circles from a rearrangement between the two  $J\alpha$  gene segments. The absence of  $J\alpha 19^-/J\alpha 57^+$  clones indicated once again that there was no chromosomal DNA contaminant in the library.

To obtain probes for the mouse  $\delta$ -chain locus, which is located about 75 kilobases (kb) 5' of the  $C\alpha$  gene segment<sup>5,6</sup>, we used a restriction fragment derived from the most 5' end of the cosmid clone TA28.1 (ref. 9) to isolate further cosmids (Fig. 1). Probes were derived that would hybridize to regions 5' to the  $D\delta 2$  gene segment (probe A), within the  $D\delta 2$ - $J\delta 1$  intron (probe B) and 3' of the  $J\delta 1$  gene segment (probe C) (Fig. 1). Because all three probes are contained in a single 7.4-kb *EcoRI* restriction fragment, we anticipated that clones from the  $\alpha$ -chain circles containing the germline configuration of the  $\delta$ -chain would hybridize to all three probes, whereas clones containing rearranged  $\delta$  segments would hybridize to a subset of the probes, except in the case of a rearrangement to the  $J\delta 2$  gene segment, which would give no fragment.

Each of the probes we tested hybridized to >500 clones in the larger library and to 48 clones in the smaller. The number of  $J\delta 1$ -positive clones was in agreement with what would be expected from a circle library with many  $J\alpha$  positives, because a  $J\delta$  probe will detect all the  $\alpha$ -circles and a single  $J\alpha$  probe will only detect a proportion of the  $\alpha$ -circles. (Okazaki and Sakano<sup>10</sup> have earlier reported analysing a circle library in which they detected only 5  $J\delta$  positives and >200  $\alpha$ -positives with a single  $J\alpha$  probe. This apparent conflict with our results may reflect the loss of  $J\delta 1$  clones during the amplification step used in the construction of their library. Our libraries were not amplified at the time of the analysis). All clones that hybridized

FIG. 2 Southern genomic blots of mouse liver DNA and various mouse thymus DNAs, using the probes D and E depicted in Fig. 1. Probes D and E hybridized to thymus DNAs from days 16, 17 and 18 of gestation, and from adult mouse. These DNAs were digested with several different restriction enzymes spanning the  $C\delta$ - $J\alpha 1$  region (*EcoRI* and *KpnI* for probe D, and *EcoRI* and *BamHI* for probe E, see Fig. 1). This allowed us to detect any moderately frequent rearrangement into the region between the  $C\delta$  and  $J\alpha 1$  gene segments.

to probe C also hybridized to probes A and B (Table 1). There were also a few clones scoring  $A^+C^-$  (these were isolated in early screening and were not tested with the B probe) and  $B^+C^-$  (not tested with the A probe). We isolated several  $A^+B^+C^+$  clones whose restriction fragments were indistinguishable from the germline structure presented by cosmid clone TA9. Although this result strongly implies that the  $\alpha$ -circles have a germline  $\delta$ -chain gene configuration, there are two types of circle arising from  $\delta$ -chain gene rearrangements that could also score as positives: rearrangements to  $J\delta 1$  and  $VD\delta 2$  rearrangements would give  $A^+B^+C^-$  ( $VJ\delta 1$  or  $VD\delta 1J\delta 1$  circles),  $A^+B^+C^-$  ( $D\delta 2J\delta 1$  or  $VD\delta 2J\delta 1$  circles) or  $A^+B^+C^-$  ( $VD\delta 2$  or  $VD\delta 2J\delta 1$  circles) and rearrangements to the  $J\delta 2$  gene segment would give  $A^+B^+C^+$  ( $D\delta 1J\delta 2$  or  $VJ\delta 2$  circles) or  $A^+B^+C^+$  ( $D\delta 2J\delta 2$  or  $VD\delta 2J\delta 2$  circles). The small number of  $C^-$  cases in our library (Table 1), however, in conjunction with the fact that the number of rearrangements to  $J\delta 2$  was at most 1/10 of those to  $J\delta 1$  (ref. 6), indicated that most  $A^+B^+C^+$  clones were derived from  $\alpha$ -circles. We conclude that the  $\delta$ -chain gene is in the germline configuration in the circle products of the  $\alpha$ -chain gene rearrangement.

To determine whether a rearrangement analogous to the T-early- $\alpha$  rearrangement—which takes place between a region 5' to the  $D\delta 2$  gene and a  $\psi J\alpha$  region several kb upstream of the most 5' of the  $J\alpha$  gene segments of the human  $\alpha/\delta$  gene locus<sup>11,12</sup> also occurs in the mouse  $\alpha/\delta$  locus, we performed Southern genomic blots of mouse thymus DNA using probes lying immediately 5' of the  $J\alpha 1$  gene segment (probes D and E in

FIG. 1 Schematic diagram of the T-cell antigen receptor  $\alpha$ -chain and  $\delta$ -chain gene locus. TA3 and TA9 were obtained using a restriction fragment from the most 5' end of the TA28.1 cosmid clone<sup>9</sup> to screen an AKR cosmid library constructed in the pTL5 vector<sup>14</sup>. A plus sign indicates the presence of additional restriction enzyme sites. Probes A, B and C were derived from a subclone containing the 7.4-kb *EcoRI* fragment of the cosmid clone TA9. Probe A was a 1-kb *XbaI/PvuII* fragment, probe B was a 360-base pair *HindIII/PvuII* fragment and probe C was a 2-kb *SacI* fragment. Probes D and E were derived from the cosmid clone TA28.1. Probe D was a 2-kb *KpnI/HindIII* fragment and probe E was a 1.2-kb *EcoRI/BglII* fragment.

Fig. 1). Probes D and E, however, both detected only the germline bands and no rearranged fragments, even after the blots were exposed for a long time (Fig. 2). In contrast to the human T-early- $\alpha$  rearrangements, which were readily detectable in a Southern genomic blot of human thymus DNA, we found no analogous rearrangement in the mouse and so conclude that the majority of the circle DNAs we analysed came from the  $\alpha$ -chain rearrangement products.

Our results help to clarify the scheme of T-cell differentiation. It has previously been suggested that progenitor thymocytes initially attempt to rearrange the genes for  $\gamma$ - and  $\delta$ -chains; when they fail to produce functional  $\gamma\delta$  receptors, the cells then rearrange their  $\alpha$ - and  $\beta$ -chain genes<sup>13</sup>. This model is inconsistent with our analysis of the  $\delta$ -chain gene rearrangement status in the  $\alpha$ -circles, which indicates that a majority of  $\alpha$ -producing T cells have never rearranged their  $\delta$ -chain locus. Thus T cells expressing  $\alpha\beta$  and  $\gamma\delta$  receptors are not in the same developmental lineage. The split of  $\alpha\beta$ - and  $\gamma\delta$ -producing T-cell lineages could occur after the initial  $\gamma$ -chain gene rearrangements, known to start at day 14 of gestation. Cells with a productive  $\gamma$ -chain gene rearrangement would go on to rearrange their  $\delta$ -chain gene, whereas cells with a non-productive  $\gamma$ -chain gene rearrangement would then differentiate to the  $\alpha\beta$

lineage. Alternatively and perhaps more probably, the T-cell lineage decision would be made independently of the rearrangement process, with one subset of T cells committing to  $\alpha$ -chain rearrangement and another subset to  $\delta$ -chain rearrangement. Rearrangements at the  $\gamma$ -chain gene and the *DJ* of the  $\beta$ -chain gene might then happen in both lineages because of a lack of precise control over these particular events. □

## ***Distal-less* encodes a homoeodomain protein required for limb development in *Drosophila***

Stephen M. Cohen\*, Günter Brönner\*, Frank Küttner\*, Gerd Jürgens\* & Herbert Jäckle\*

Max-Planck-Institut für Entwicklungsbiologie, Spemannstr. 35, 7400 Tübingen, FRG

THE spatial organization of the *Drosophila* embryo depends on the activity of three axial pattern-forming systems. In addition to the anterior-posterior and dorsal-ventral systems that organize the segmented body plan<sup>1</sup>, a proximal-distal pattern-forming system is required to provide positional information for the developing limbs. The development of both the larval and adult limbs depends directly on the activity of the *Distal-less* gene<sup>2,3</sup>. Genetic analysis has shown that *Distal-less* functions as a developmental switch that is required to promote the development of limb structures above the evolutionary ground-state of body wall. Here we provide genetic evidence that indicates a graded requirement for *Distal-less* activity during limb development. Reduction of this activity has a global effect on pattern formation in the limb. The molecular structure of the *Distal-less* locus indicates that the gene encodes a homoeodomain-containing protein which is therefore likely to specify limb development through differential regulation of subordinate genes.

The normal development of *Drosophila* limbs depends on the activity of the *Distal-less* (*Dll*) gene. Several mutations that reduce, but do not completely eliminate, *Dll* activity permit survival to adulthood but cause developmental abnormalities in the adult limbs<sup>3</sup>. Examination of the effects of these alleles on the adult leg shows a progressive pattern of developmental abnormalities that reflects the spatial requirement for *Dll* activity during limb development (Fig. 1). The range of severity of phenotypes caused by different alleles indicates that there is a

graded requirement for *Dll* activity in the developing leg. The most striking feature of these phenotypes is that progressively stronger alleles do not cause deletion of discrete structures in a simple distal to proximal series. Rather, structural elements are lost concomitantly from broad regions of the pattern so that the different regions of the limb are still present but are reduced in size and fused together (Fig. 1*b–d*). These results indicate that reducing *Dll* activity alters the pattern of the developing limb as a whole and suggest that the gene may therefore be responsible for organizing this pattern.

The formal genetic requirement for a graded activity of the gene does not in itself imply that the product need be distributed in a concentration gradient within the developing limb primordium. The ability of individual cells to develop into limb structures, however, depends directly on their own ability to express *Dll*<sup>2</sup>. In this context, the graded requirement for *Dll* expression in individual cells suggests that the concentration of the *Dll* gene product is directly involved in specifying positional information along the proximal-distal axis of the limb.

To assess this prediction we undertook a molecular analysis of the *Dll* locus. We cloned the region by chromosomal walking and mapped the molecular lesions associated with eight alleles (Fig. 2*a*). These lesions are evenly distributed through about 38 kilobases (kb) of DNA in which only a single transcription unit, encoding transcripts of ~2.5 and ~3.4 kb, can be detected (Fig. 2*b–d*). Non-contiguous restriction fragments distributed over ~25 kb of the genomic DNA detect the same pair of transcripts. As these transcripts are rare (<10% the level of *engrailed*) we have been unable to isolate full-length complementary DNA clones and can only infer that primary transcripts derived from this relatively large region of genomic DNA are spliced to produce the messenger RNAs detected by the various probes (Fig. 2*e*).

The activity of *Dll* is known to be required during embryogenesis, as amorphic embryos fail to develop larval limbs<sup>2,3</sup>. The precise time during embryogenesis at which the larval and imaginal limb primordia become determined however, is unknown. The vestigial larval limbs are peripheral sense organs<sup>2</sup> which develop during late embryogenesis, following germ band retraction<sup>4</sup>. The putative *Dll* transcripts are first detectable at low levels in post-blastoderm embryos and, as expected, at increased levels during late embryogenesis. Expression of the gene is also required in the developing limb imaginal disk primordia<sup>2</sup>. The transcripts are expressed during the first larva

FIG. 1 Deletions of pattern elements in the legs of partial loss-of-function *Dll* mutants. *a*, A wild-type male foreleg. Coxa is the most proximal leg segment and develops independently of *Dll* activity<sup>2</sup>. The more distal segments of the appendage are the limb proper<sup>23</sup>. Abbreviations are: tr, trochanter; fe, femur; ti, tibia; mt, metatarsus (also called basitarsus); ta, tarsal segments 2-5; c, claw; p, pulvillus. In the weakest alleles (P and M, for example) only minor reductions in the tarsal region can be detected (not shown). Alleles of moderate severity (IB, 6, 7, 8) cause more extreme reduction of tarsal structures and fusion between tarsal and tibial elements. *b*, Foreleg of a male homozygous for *Dll*<sup>IB</sup>. The metatarsus and tibia are fused. The sex comb of the metatarsus (arrow) and the transverse rows of bristles normally found on the tibia are now found on a common segment (ti-mt), and are both reduced. A single nondescript tarsal segment remains distally. *c*, The leg of a *Dll*<sup>7</sup> homozygote. Note the fused metatarsus and tibia (ti-mt). *Dll*<sup>7</sup> homozygotes typically have normal second tarsal segment (ta2) and a bulbous distal tarsal blob (ta). *d*, Foreleg of a male of the most extreme viable genotypic combination *Dll*<sup>3</sup>/*Dll*<sup>SA1</sup>. Note the greatly reduced femur and tibia associated with normal trochanter and coxa.

All independent tarsal segments seem to be deleted. In rare cases of a milder genotype *Dll*<sup>3</sup>/*Dll*<sup>3</sup> an occasional sex comb tooth can be detected on the most distal segment, which suggests that this structure may be a fused metatarsus-tibia. Analogous defects also observed in the other segmented appendages of the *Drosophila* adult: the antenna, the maxilla, the labium and

the labrum. Detailed morphological descriptions of the *Dll* hypomorphic phenotypes in these appendages will be presented elsewhere (S.M.C. and G.J., manuscript in preparation).

METHODS. Adult cuticle preparations were as previously described<sup>2</sup>. Some of the *Distal-less* alleles used here have been described previously under the name *Brista*<sup>3</sup>. We have retained the previous allele designations. The origins of the other alleles will be presented elsewhere (S.M.C. and G.J., manuscript in preparation).

FIG. 2 Molecular organization of the *Dll* locus at cytogenetic map position 60E5.6 in chromosome 2R. *a*, The molecular locations of chromosomal rearrangements associated with *Dll* alleles are indicated by filled boxes. The size of the black boxes indicates the extent of the deletions in the alleles MP and SA1. The size of the hatched boxes indicates the uncertainty in the exact location of the breakpoints of the translocations W and J, the transposition G, the insertions P and *En(Arp)* and the inversion B. Open boxes indicate the locations of rearrangements that genetically define a distal limit for the *Dll* locus. *En(Arp)* was generated in a hybrid dysgenic screen (P. Adler) and contains two independent insertions in the region: an insert of 8-kb of DNA associated with the mutation and a P-element near coordinate 30 which lies outside the gene (defined by the breakpoint of *Df(2R)ES1* which is *Dll*<sup>+</sup>). C and T indicate direction of centromere and telomere. The location and orientation (where known) of transcription units within the interval between 60- and 160-kb are indicated. *b*, Reduced stringency hybridization to genomic DNA from *D. melanogaster* (lanes 1, 3) and *D. virilis* (lanes 2, 4) was used to locate coding sequences<sup>24</sup>. The two species are diverged by ~60 million years<sup>25</sup>. Lanes 1 and 2 were probed with the 1.6-kb *SalI*-*XbaI* fragment (stippled box in *e*) located within the DNA removed by the 5.5-kb deletion associated with the SA1 allele. Lanes 3 and 4 were probed with the 2-kb *HindIII*-*SalI* fragment flanking the deletion. Note that although both probe fragments hybridize to the same 6.6-kb genomic *SalI* fragment in the *D. melanogaster* DNA, only the 1.6-kb *XbaI*-*SalI* probe detects a conserved sequence in the *D. virilis* DNA. *c*, Transcription of the *Dll* locus. 10 µg of poly(A)<sup>+</sup> RNA from 0-4 h embryos, 4-8 h embryos, 8-20 h embryos, and first, second and third instar larvae (L1, L2 and L3) in lanes 1-6, respectively, were hybridized with the 1.4-kb *EcoRI* fragment encoding the 3' region of the transcript (indicated by the diagonally striped box in panel *e*). *d*, Same filter as *c*, rehybridized with a tubulin cDNA clone. Note that the apparent concentration of the *Dll* RNAs in the 8-20 h sample under-represents the actual relative level because this lane is underloaded. *e*, Location of the proposed *Dll* exons on the physical map of the locus. Restriction fragments that hybridize strongly to the transcripts in *c* are indicated by filled boxes below the map. B, *Bam*HI; H, *Hind*III; P, *Pst*I; R, *Eco*RI; S, *Sal*I; X, *Xba*I. Within the 870-base pair (bp) *SalI*-*Bam*HI fragment both the 500-bp *SalI*-*Pst*I and the adjacent 370-bp *Pst*I-*Bam*HI subfragments hybridized to the transcript. DNA sequence analysis reveals an open reading frame spanning the *Pst*I site that has the capacity to encode part of a homeodomain. The locations of the transcribed sequences are consistent with the molecular lesions associated with the amorphic alleles. *Dll*<sup>MP</sup> is a large deletion which removes the entire coding region. The small deletion SA1 removes a single exon. The deletion in the SA1 chromosome does not exist in the parental chromosome from which the mutant line was derived and is therefore likely to be the direct cause of the mutant phenotype. The fragments in which the breakpoints of other alleles are located are indicated by lines above the map. The translocation allele W and the inversion B would prevent correct splicing of the mature transcript. The insertion of ~8-kb into the ~13-kb intron in the *En(Arp)* allele also causes an amorphic phenotype. The translocation breakpoint in the allele J is located 3' to the proposed coding region.

METHODS. Molecular breakpoints of the chromosomal rearrangements were determined by *in situ* hybridization to polytene chromosomes using biotinylated probes<sup>26</sup> and by genomic Southern hybridization. The origins and genetic properties of the alleles are described in ref. 2. Reduced-stringency Southern blots were washed in 1 × SSPE at 65 °C. RNAs were fractionated on formaldehyde agarose gels, transferred to nylon and hybridized with <sup>32</sup>P-labelled probes generated by random priming of gel-purified restriction fragments. The orientation of transcription was determined using single-stranded RNA probes and by DNA sequence analysis of short cDNA clones from the 3' ends of the transcripts (not shown).

FIG. 3 Sequence comparison of the *Dll* and other homoeodomains. Dashes indicate sequence identity with *Dll*. The positions of the  $\alpha$ -helices determined by NMR analysis of the antennapedia protein<sup>27</sup> are indicated. Boxed residues correspond to solvent-exposed residues involved in sequence-specific contact to the DNA in the bacterial helix-turn-helix proteins<sup>28</sup>. Amino-acid residues conserved in all characterized *Drosophila* homoeodomains are indicated above the *Dll* sequence. The *Dll* HD is diverged from other *Drosophila* HDs with a maximum of 48% amino acid identity to *engrailed*<sup>29,30</sup>, *AbdB*<sup>31</sup> and

*zen2*<sup>32</sup>. In spite of lower overall sequence identity to *labial*<sup>9</sup> (46%) meaningful similarity is greater in that both are interrupted by an intron between residues 44 and 45 (arrow). Other HDs shown for comparison are *rough*<sup>33</sup>, which specifies cell identity in eye development and is like *labial*, and the *Xenopus* *XlHbox1* HD<sup>13</sup>, which may play a role in vertebrate limb development (indicated as XI). Note that this protein, and its newt and human homologues (not shown), are less similar to *Dll* than they are to other *Drosophila* HDs such as *labial*.

instar, at reduced levels during second instar and at higher levels during third instar. The biphasic expression profile is consistent with the requirements for *Dll* activity in development of the larval and adult appendages<sup>2,3</sup>.

The DNA sequences of the genomic fragments that hybridize to the transcripts were determined. A potential protein-coding region was found that has the capacity to encode a polypeptide containing the first 44 amino acids of the homoeodomain (HD), a DNA-binding protein motif found in several developmental regulatory genes of *Drosophila*, yeast and vertebrates<sup>5-7</sup>. The predicted protein sequence diverges significantly from the HD consensus at the position of a potential splice donor site located in the putative DNA-binding helix, and the open reading frame terminates soon thereafter, which suggests that the recognition helix is interrupted by an intron. The remainder of the HD was located in the next more 3' DNA fragment hybridizing to the RNA. This proposed exon was located as an open reading frame following a splice acceptor site which would, if used, complete the HD (Fig. 3). Although we have no direct evidence that the ~13-kb intron is spliced in this way from the *Dll* transcript, the most highly conserved region of most HDs<sup>8</sup> is located 3' to the proposed splice acceptor site. Precedent exists in the case of the *labial* gene of *Drosophila*, which is spliced at precisely the same position in the HD<sup>9</sup>. Several HD-containing proteins bind to DNA in a sequence-specific manner<sup>6,10-16</sup>, and in some cases DNA-binding activity has been shown to reside in the homoeodomain<sup>6,10,16,17</sup>. At present we have too little information about the structural basis for sequence-specific DNA-binding of *Drosophila* HD proteins to assess the significance of the rather divergent amino-acid sequence of the *Dll* HD (Fig. 3).

Recently two other HD-encoding gene products have been shown to exhibit spatial expression patterns consistent with a role for these genes in limb development. The *Xenopus* *XlHbox1* protein (and its murine homologue) are distributed in a concentration gradient along the anterior-posterior axis in the mesoderm of the developing frog and mouse forelimb buds, respectively<sup>18</sup>. The newt homologue of these genes *NvHbox1* is differentially expressed along the proximal-distal axis of the regenerating newt limb<sup>19</sup>. The patterns of expression of these gene products indicate that they play a part in development of the vertebrate limb which is different from that played by *Distal-less* in the *Drosophila* limb. The vertebrate proteins are, in fact, more closely related at the amino-acid sequence level to other *Drosophila* HDs such as *labial* than they are to the *Dll* protein (Fig. 3).

The molecular characteristics of the putative *Dll* gene product are consistent with its proposed genetic function. The graded

requirement for the activity of the *Dll* locus for development of the proximal-distal pattern of the limbs is analogous to the graded requirement for the activity of *bicoid* along the anterior-posterior axis of the *Drosophila* embryo<sup>20</sup>. The graded requirement for *bicoid* activity correlates with a graded distribution of the gene product in the early embryo<sup>21,22</sup>. A graded distribution of the *Dll* protein provides the simplest explanation for the genetic results, although we emphasize that this is not the only possible explanation. If such a gradient exists, the mechanism by which it is established will certainly be different from the simple diffusion mechanism that has been proposed to establish the *bicoid* gradient<sup>21</sup>, as a gradient of the *Dll* protein would have to be established in a field of epithelial cells, rather than in a field of naive nuclei occupying a common cytoplasm. Because the *Dll* protein contains a homoeodomain, it is tempting to speculate that the concentration of the product might, like *bicoid*, directly specify positional information through differential regulation of subordinate genes. □

# Increased $\gamma$ -globin expression in a nondeletion HPFH mediated by an erythroid-specific DNA-binding factor

David I. K. Martin, Shih-Feng Tsai & Stuart H. Orkin

Division of Hematology-Oncology, Children's Hospital, and the Dana Farber Cancer Institute, Department of Pediatrics, Harvard Medical School, Howard Hughes Medical Institute, Boston, Massachusetts 02115, USA

IN man, a shift from  $\gamma$ - to  $\beta$ -globin gene expression in erythroblasts underlies a switch from fetal to adult haemoglobin during development<sup>1</sup>. In hereditary persistence of fetal haemoglobin (HPFH), inappropriately high  $\gamma$ -globin expression in adult life is associated with deletions in the  $\beta$ -globin cluster or with single-base changes upstream of the  $\gamma$ -globin genes. To account for enhanced  $\gamma$ -gene expression in HPFH of the non-deletion type, we tested the nuclear proteins of human erythroleukaemia cells<sup>2</sup> that bind  $\gamma$ -promoter sequences *in vitro* by correlating specific mutations in their binding sites with promoter activity. An erythroid-specific factor (GF-1) binds as a single molecule to the -195 to -170 region and contacts two TATCT(AGATA) motifs, but not the conserved octamer (ATGCAAAT)<sup>3-8</sup> that separates them. We observe that a single change (at -175, T  $\rightarrow$  C) found in HPFH<sup>9,10</sup> leads to increased promoter activity only in erythroid cells. This effect is mediated by GF-1, the human counterpart of the chicken erythroid factor<sup>11</sup> Eryf 1. The form of HPFH we studied here is an inherited disorder which can be ascribed to the action of a cell-specific DNA-binding factor on a mutant promoter.

Using  $\gamma$ -globin-producing human erythroleukaemia (K562) cells, we sought nuclear factors which bind *in vitro* to a -257 to -140  $\gamma$ -promoter fragment that contains the octamer<sup>12,13</sup>, activates a linked  $\beta$ -globin gene on transfer into K562 cells<sup>14</sup>, and is the site of all but one of the single-base changes known to be associated with HPFH<sup>1</sup>. Two types of binding activity were detected (Fig. 1a): one produces gel-retardation complex 2A, is found in all cell lines and is identical to the ubiquitous octamer-binding factor NF-A1/OTF-1; the other gives rise to complexes 1A/1B, is produced only by erythroid cell extracts and is termed GF-1. Binding specificities were distinguished by competition for gel-retardation complexes (Fig. 1b). The core octamer sequence, but not a heterologous sequence or DNA containing the -175 T  $\rightarrow$  C HPFH substitution, inhibited formation of complex 2A. Conversely, complexes 1A/1B were competed out by DNA with the -175 T  $\rightarrow$  C substitution, but not by the core octamer or a heterologous sequence. All complexes were specifically competed out by homologous DNA. Figure 2(a-e) summarizes DNase I footprinting<sup>15</sup> and methylation interference<sup>16</sup> assays of crude and fractionated K562 and HeLa nuclear extracts. Fractions yielding complex 2A (of K562 or HeLa origin) protect and contact nucleotides of the core octamer, consistent with its designation as NF-A1/OTF-1. Fractions containing activity-generating complex 1A/1B protect sequences extending from -195 to -170 and induce hypersensitive sites (Fig. 2a, b). Although the octamer is protected by binding of the erythroid-specific factor, DNA contact sites (Fig. 2c and d) are found only in the flanking sequences.

Several features of the binding of GF-1 to the  $\gamma$ -promoter merit discussion. GF-1 directly contacts repeats of five bases (TATCT or AGATA) in the footprinted region (Fig. 2e). These encompass positions -189 to -185 and -175 to -171. The similarity of DNA contact sites in these repeats suggests two regions that might bind one or two protein molecules. Although two GF-1 molecules could possibly bind to the two motifs in the -195 to -170 region, the following mutation analysis indicates that only a single molecule binds to generate complex 1A.

Complex 1B can be resolved into two species on gels (Fig. 3a): both result from binding of proteolytic fragments of GF-1 (our unpublished data). C  $\rightarrow$  A substitutions at contact sites in either motif (-186 or -172) abolish one or other of the two 1B species. These mutations reduce, but do not abolish, complex 1A. A methylation-interference assay (Fig. 2d) shows complete interference of both motifs in complex 1A. If complex 1A contained two bound GF-1 molecules, either mutation (-186 or -172) would be expected to completely abolish complex 1A and also to generate a faster migrating complex, which is not observed. Furthermore, gel-retardation with probes containing single binding motifs from other globin promoters and enhancers produce complex 1A as the chief species (not shown). A double mutation at -186/-172 abolishes binding to the A $\gamma$ -promoter (Fig. 3b). We conclude that a single GF-1 molecule interacts with a bipartite binding site in the  $\gamma$ -promoter and mutations in either motif can influence formation of the protein-DNA complex.

Evans *et al.*<sup>11</sup> recently described an erythroid-specific globin DNA-binding activity in chickens (Eryf 1) which recognizes a proposed consensus (A/T)GATA(A/G). GF-1 and the independently identified human factor NF-E1 (refs 17 and 18) seem to be the counterpart of this chicken factor. The specific competition for GF-1 binding to the  $\gamma$ -promoter by sequences derived from the 3'- $\beta$ -globin enhancers of chicken or human origin

FIG. 1 Detection of DNA-binding activities in K562 and HeLa cell nuclear extracts. a, Gel-retardation assay of crude K562 and HeLa nuclear extracts incubated with a 117-base pair (bp) *HinfI/NcoI* fragment (-257 to -140) of the A $\gamma$ -globin gene<sup>19</sup> promoter. Complexes 1A/1B have been observed only with nuclear extracts of K562, HEL and MEL cells and were absent in human B- and T-lymphoid lines (EBV-line 721 and MOLT 4), monocytic U937 and THP-1, human myeloid HL60 and PLB-985, and murine myeloma cells (P3X) (not shown). b, Competition of gel-retardation complexes by double-stranded oligonucleotides. Heparin-Sepharose-fractionated K562 cell nuclear extract was used in gel-retardation assays with the *HinfI/NcoI* fragment without added competitor (-), or with addition of 20 ng (400-fold excess) double-stranded oligonucleotides (lanes 1-4). The oligonucleotides were as follows: lane 1, a 26-bp  $\gamma$ -promoter sequence from -195 to -169; lane 2, a 32-bp sequence containing four repeats of the ATGCAAAT motif; lane 3, a 26-bp sequence identical to that in lane 1, except for a T  $\rightarrow$  C replacement at -175; and lane 4, a 39-bp sequence extending from -140 to -101 of the  $\gamma$ -promoter, which does not share sequences with the *HinfI/NcoI* fragment. For analysis of complexes 1A and 1B we used a 0.1 M (flow-through) heparin-Sepharose fraction, and a 0.2 M fraction for complex 2A.

**METHODS.** Nuclear extracts were prepared as described<sup>27</sup>. For preparation of K562 extract it is necessary to include leupeptin, pepstatin and aprotinin in addition to phenylmethyl sulphonyl fluoride to inhibit proteolysis. Fractionation on heparin-Sepharose was by loading crude extract in buffer D<sup>27</sup> containing 0.1 M KCl at 4 °C. Step elutions with buffer D containing 0.2 M, 0.3 M, and 1.0 M KCl were carried out after collection of the flow-through (0.1 M). The 117-bp *HinfI/NcoI* fragment of the A $\gamma$ -promoter<sup>19</sup> was 5'-end-labelled and prepared by standard methods<sup>28</sup>. Gel-retardation assays<sup>29,30</sup> were performed on ice in 20  $\mu$ l containing 1  $\mu$ l (0.5-5  $\mu$ g) crude or fractionated extract, 1-5  $\mu$ g poly (di-dC), and 10<sup>4</sup> d.p.m. end-labelled DNA (0.2 ng) in 10 mM HEPES, pH 7.8, 50 mM potassium glutamate, 5 mM MgCl<sub>2</sub>, 1 mM EDTA, 1 mM dithiothreitol and 5% glycerol. Incubation was for 30 min on ice. Reactions were loaded on to 0.5  $\times$  Tris-borate-EDTA/5% polyacrylamide gels and electrophoresed at 10 V per cm for 2 h at 4 °C.

supports this conclusion (Fig. 3c). In contrast with our results for the  $\gamma$ -promoter, the two Eryf 1 binding sites in the chicken 3'- $\beta$ -globin enhancer act independently<sup>11</sup>. Although the motifs are comparably spaced in the two elements, their orientations are opposite in the chicken  $\beta$ -enhancer, but the same in the  $\gamma$ -promoter. GF-1 binding *in vitro* (Fig. 3c) seems to be dominant over NF-A1 (OTF-1) binding in crude extracts and excludes simultaneous occupancy by this ubiquitous factor on the promoter.

We evaluated the relevance of the binding of two factors *in vitro* with overlapping sequences in the -195 to -170 region to the enhanced expression of  $\gamma$ -globin in HPFH. Promoter activity was assayed in a transient expression system in which wild-type and mutant promoters (encompassing sequences from -385 to +50 of the  $A_\gamma$  gene<sup>19</sup>) linked to the human growth hormone (GH) gene<sup>20</sup> as a reporter were introduced into K562 cells (which synthesize  $\gamma$ - and  $\epsilon$ -, but not  $\beta$ -globins),  $\beta$ -globin-producing mouse erythroleukaemia (MEL) cells, and non-erythroid cells. When introduced into K562 and MEL cells in supercoiled plasmid, the -175 T $\rightarrow$ C HPFH promoter directed production of 4.4 and 4.8 times as much growth hormone as the wild-type respectively ( $P < 0.001$ ). Expression directed by the mutant promoter was not increased in two non-erythroid cell

lines, HeLa and PLB-985<sup>21</sup>. As the -175 T $\rightarrow$ C substitution greatly reduces binding of NF-A1/OTF-1 *in vitro*<sup>17</sup> (Fig. 1), it has been proposed that alleviation of negative regulation by this factor might account for the HPFH phenotype of the -175 T $\rightarrow$ C mutant<sup>12,13</sup>. Evidence against this model was provided by mutant promoters with other substitutions in the octamer. Expression was not enhanced by either a triple substitution (GCA $\rightarrow$ AAG at -180 to -178) or a single-base change (C $\rightarrow$ A at -179) in the octamer. *In vitro* binding to these mutant promoters by the octamer-binding factor, but not by GF-1, is drastically reduced (not shown). The role of GF-1 was investigated by mutating its DNA contact sites flanking the octamer in the context of the wild-type and -175 T $\rightarrow$ C promoters. Introduction of C $\rightarrow$ A substitutions at -186 and -172 or a single C $\rightarrow$ A change at -186 in the -175 T $\rightarrow$ C promoter reduced expression in K562 to the wild-type level. From these transient expression experiments we conclude that (1) the -175 T $\rightarrow$ C HPFH substitution increases promoter strength in erythroid cells of either fetal/embryonic (K562) or adult (MEL) type; (2) the altered expression of the -175 T $\rightarrow$ C promoter in erythroid cells is not due *per se* to reduced binding of a negatively acting octamer-binding factor; and (3) enhanced, erythroid-specific expression of the -175 T $\rightarrow$ C promoter depends on binding of GF-1.

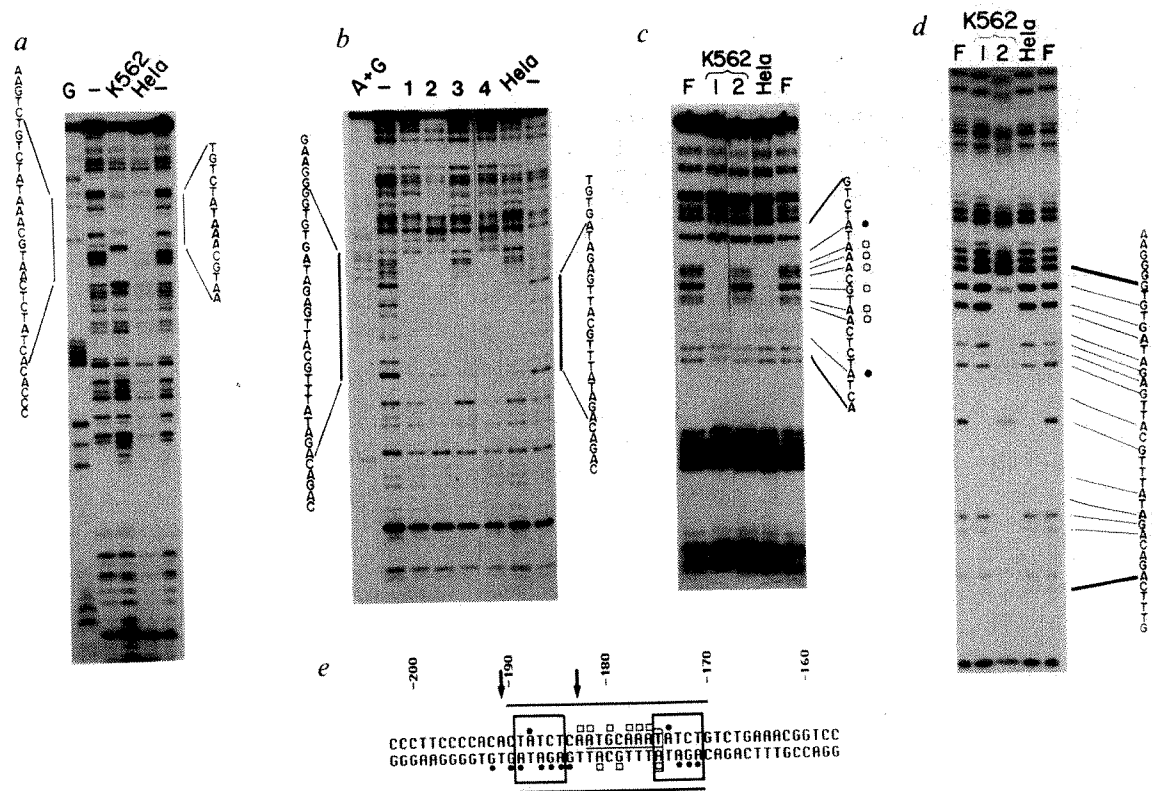

FIG. 2 DNase I footprinting and methylation interference assay of the two DNA-binding activities present in K562 nuclear extracts. *a* and *b*, DNase I footprinting of the HinfI/NcoI  $\gamma$ -globin promoter fragment by K562 and HeLa cell nuclear extracts. Coding (*a*) and non-coding (*b*) strands of the 117-bp fragment were digested with DNase I as described below. Maxam-Gilbert sequencing reactions are shown to the left in each panel. DNase digestions without added protein are denoted as (-). *a*, Crude nuclear extracts of K562 and HeLa are presented. *b*, Crude (lane 1) and heparin-Sepharose fractionated K562 (0.1 M, 0.2 M and 1.0 M fractions, lanes 2-4) extracts and crude HeLa extract. Footprinted areas are denoted by the vertical lines at the left (K562) and right (HeLa) of each panel. For heparin-Sepharose fractionated K562 extracts, DNase I footprints obtained with 0.1 M and 1.0 M fractions are considered equivalent, as we subsequently found that the flow-through (0.1 M) fraction could be quantitatively bound and eluted from the column in the 1.0 M fraction (not shown). *c* and *d*, Methylation interference assays of complexes. G $\rightarrow$ A sequence of unbound (F) fragment DNA is shown for

reference. Interference patterns in K562 complex 2A (lane 1) and complex 1A (lane 2) and HeLa complex 2A (HeLa lane) are shown for the coding (*c*) and non-coding (*d*) strands. Open squares denote methylated bases that interfere with binding in complex 2A; closed circles denote methylated bases interfering with complex 1A. The DNase I footprints and methylation interference DNA contact sites are summarized in *e*. Horizontal lines denote the sequences on each strand protected by K562 extract (total or 0.1 M/1.0 M fractions). Duplicated and contacted TATCT (AGATA) motifs straddling the conserved octamer are boxed. Downward arrows indicate the positions of DNase-hypersensitive sites.

METHODS. DNase I footprinting was as described<sup>15</sup>. Binding was in 50  $\mu$ l containing  $2.5 \times 10^4$  d.p.m. end-labelled DNA, 1-5  $\mu$ g poly (dI-dC), and 5-50  $\mu$ g crude or fractionated nuclear extract in 10 mM HEPES, 1 mM dithiothreitol, pH 7.8, 50 mM potassium glutamate, 5 mM MgCl<sub>2</sub>, 1 mM EDTA, 5% glycerol and 2% polyvinyl alcohol. Methylation interference assays<sup>31</sup> and end-labelled probe methylated<sup>32</sup> were as described.

Whereas enhanced expression seems to require potential GF-1 contact sites, mutations at -186, -172, or -186/-172 revealed no effect on transient expression in the context of the wild-type promoter. As  $\gamma$ -GH constructs have a basal promoter activity which is not cell-type specific, we also assessed the role of GF-1 binding in the -195 to -170 region on the  $\gamma$ -promoter function, using a stable selection assay which exhibits greater tissue-specificity<sup>22</sup>.  $\gamma$ -Promoter/neomycin-resistance gene constructs were introduced into K562 cells and the number of G418-resistant colonies was scored. Consistent with the transient expression data, the -175 T→C/*neo* plasmid yielded 3.1 times more G418-resistant colonies than the wild-type construct ( $P<0.01$ ). C→A mutations at -186/-172 in the presence or absence of the -175 base change reproducibly reduced the frequency of G418-resistant clones 40–50% (relative to wild-type) ( $P<0.05$ ). Additional regulatory elements in the -385 to +50 promoter fragment (outside the -195 to -170 region) thus contribute to its erythroid specificity.

Although GF-1 is implicated in the enhanced activity of the -175 T→C mutant promoter, no major difference in its binding was apparent in the retardation assay (Fig. 3b). It has been suggested that affinity of the -175 T→C mutant promoter for

(presumably) the same erythroid-specific factor is increased 5-fold<sup>17</sup>, but we do not find this. Using either crude or fractionated nuclear extracts, we observe no difference in the affinity of GF-1 for the two promoters (Fig. 4a, b). This finding has recently been supported independently<sup>23</sup>. Although the -175 substitution alters the proximal TATCT motif to CATCT, GF-1 still binds strongly to the proximal motif, as assayed by methylation interference (ref. 17 and our unpublished data). Disruption of the proximal motif, either alone or in combination with a substitution in the octamer (C→A at -172 and C→A at both -172/-179), does not mimic the effect of the -175 T→C mutation on expression. But the DNase I footprint of the mutant promoter shows reduced protection of the proximal motif, which implies an altered recognition of the bipartite site by GF-1 (Fig. 4c). Finally, we have observed that linearization of the -175 T→C promoter/*GH* construct before transient expression in K562 cells largely abolishes enhanced expression.

How then does the -175 T→C mutation lead to enhanced expression? Taken together, our findings suggest that the increased expression characteristic of the HPFH mutant is due to an altered interaction of the mutant promoter with GF-1. Although we find no evidence for a role for the ubiquitous

FIG. 3 Binding of GF-1 to mutant promoter DNAs and cross-competition by human and chicken 3'  $\beta$ -enhancer sequences.

a, Gel-retardation assay of K562 nuclear extract with the 117-bp *Hinf*-*Nco*I fragment of promoters containing the normal sequence (lane 1), single C→A substitutions at -186 (lane 2) and -172 (lane 3). b, Gel-retardation assay of K562 nuclear extract (0.1 M heparin-Sepharose fraction) with the 117-bp *Hinf*-*Nco*I fragment of promoters containing T→C, C→A, and C→A substitutions at -175, -186, -172, respectively (lane 1), T→C at -175 (lane 2) and wild-type sequence (lane 3). A double mutant of C→A at -186/172 in the absence of the -175 substitution behaves similarly to the triple mutant (not shown). c, Complexes formed on incubation of the wild-type *Hinf*-*Nco*I fragment with crude K562 nuclear extract (lane 1) were used to compete with ~100-fold excess of double-stranded oligonucleotides: wild-type  $\gamma$ -promoter sequence -193 to -169 (lane 2); human 3'  $\beta$ -globin enhancer TGCTGGCTCCCTATCATGTCCCTTATGGTGC (lane 3); chicken 3'  $\beta$ -enhancer

En4 (lane 4)<sup>11</sup>. Note that competition for GF-1 binding (lanes 3,4) is associated with increased NF-A1/OTF-1 binding.

FIG. 4 Interaction of GF-1 with -175 T→C HPFH DNA. In a and b, the relative affinity of K562 nuclear factors for wild-type and -175 T→C HPFH promoter sequences is compared. Competitions of formation of complex 2A (octamer-binding protein) and complexes 1A/1B (GF-1) are shown in a and b, respectively. Heparin-Sepharose-fractionated K562 extract was used in gel-retardation assays. Complex formation was competed with 0 (-), 1, 4, 10 or 20 ng unlabelled wild-type (WT) or mutant (-175 T→C) oligonucleotide (-193 to -169), as indicated. Note that the -175 T→C mutation reduces the affinity of promoter DNA for the octamer-binding factor by about 20-fold (a), but does not appreciably alter the affinity for GF-1 (b). Competition was similarly observed with larger wild-type and mutant oligonucleotides (-217 to -162) (data not shown). c, Altered binding of the -175 T→C mutant DNA to GF-1. DNase I footprinting was as in Fig. 2, except that GF-1 was purified by affinity chromatography, SDS-polyacrylamide gel electrophoresis, denaturation and renaturation. Purified GF-1 is a polypeptide of relative molecular mass 50,000 (S-F.T. and S.H.O., unpublished data). The non-coding strands of the normal (2) and -175 T→C mutant (3) are presented. DNase digestion without added protein for normal DNA (1) and -175 T→C DNA (4). The positions of the two TATCT motifs are indicated to the left. The extents of the footprints seen with the purified protein on the DNAs are depicted below with a dashed line depicting the reduced protection on mutant DNA. The

-175 mutant sequence is boxed. An additional footprint, present in the -215 region in the vicinity of a low-affinity GATA motif, is seen on both templates with purified factor.

octamer-binding protein in producing the HPFH phenotype, we do not dismiss the possibility that an octamer-binding factor may be involved in  $\gamma$ -gene regulation at some stage *in vivo*. The single base change at -175 alters the interaction of GF-1 with the promoter, rather than simply influencing their mutual affinity as assayed in gel-retardation experiments. The altered footprint of GF-1 on the HPFH mutant DNA could reflect a shift in binding from a proximal (inhibitory) site to a distal (stimulatory) site, but methylation interference demonstrates interaction with both motifs and argues against this simple model. The HPFH mutation seems to activate a region of the  $A_\gamma$ -promoter that normally contributes only a fraction of its overall activity. The effect of the -175 T→C substitution is unique in that other putative HPFH mutations (for example, at positions -202 and -196; refs 24 and 25) do not lead to striking effects on promoter strength in transient K562 or MEL cell assays (our unpublished data).

Binding motifs for GF-1 (Eryf 1, NF-E1) are widely distributed among the regulatory elements of the globin genes<sup>11,17,26</sup>. Evidence presented here and elsewhere<sup>11</sup> establishes a functional role for GF-1 in the human  $\gamma$ -promoter and in the chicken 3'  $\beta$ -enhancer. This factor acts on genes expressed at different developmental stages and, as such, may participate widely in regulation of the globin locus. Our work demonstrates that GF-1 is a positive regulator of  $\gamma$ -gene expression and that a small change in the sequence to which it binds can result in substantially increased promoter activity. If the activity of this factor when bound to DNA is dependent on the specific sequence to which it binds, elucidation of the mechanism responsible for the difference is likely to suggest how an apparently simple binding motif can participate in complex regulated gene expression. Our recent cloning of complementary DNA for GF-1 (manuscript in preparation) will facilitate more direct study of its expression, interactions with regulatory elements, and role in erythroid cell development. □

## Identification of the long ubiquitin extension as ribosomal protein S27a

Kent L. Redman\* & Martin Rechsteiner

Department of Biochemistry, University of Utah School of Medicine, Salt Lake City, Utah 84132, USA

TWO proteins of unknown function are encoded by 3' in-frame extensions of ubiquitin genes<sup>1</sup>. The polypeptides are synthesized as an additional 52 (refs 2-4) or 76-80 (refs 4, 5) amino acids on the C terminus of ubiquitin, an unusual arrangement conserved in man<sup>3,5</sup>, yeast<sup>4</sup> and plants (J. Callis and R. Vierstra, personal communication). Although not homologous to each other or to ubiquitin, both extension proteins are highly basic and contain patterns of cysteine and histidine similar to those proposed to form 'zinc fingers'<sup>6,7</sup>. The longer C-terminal extension protein (CEP80) is 30% lysine and arginine and, when denatured, behaves like a small cationic protein<sup>8</sup>. Its properties after isolation in physiological conditions, however, suggested that CEP80 is part of an RNA-protein complex. Using the antibodies that confirmed the presence of CEP80 in eukaryotic cells<sup>8</sup>, we show here that the protein located on ribosomes. Immunoblotting of rat 40S subunit proteins specifically identifies CEP80 as ribosomal protein S27a.

Native CEP80 binds to DEAE resins unless pretreated with RNase and sediments at 100,000g (K.R., unpublished results). Analysis of a rabbit reticulocyte particulate preparation on sucrose gradients showed that CEP80 was present in fractions containing 80S monosomes and polysomes (Fig. 1a). Dissociation of ribosomal subunits with salt before sedimentation shifted CEP80 to fractions containing the 40S ribosomal subunit (Fig. 1b). In the light of these results, we sought to determine whether CEP80 is one of about 30 proteins known to be components of the eukaryotic small ribosomal subunit.

Like CEP80, most ribosomal proteins are basic, but the long extension is characterized by a lysine/arginine ratio of 3. Inspection of the amino-acid compositions for 33 rat<sup>9,10</sup> and 24 *Artemia* small subunit proteins<sup>11</sup> revealed only four proteins with lysine/arginine ratios of more than 2.5 (Rat S3b, S12 and S27; *Artemia* S27a). S12 from rat is an acidic protein that does not correspond to the extension sequence<sup>12</sup>; S3b is twice the size of CEP80, as judged by SDS-PAGE<sup>10</sup>. Both rat S27 and *Artemia* S27a however, seem similar to CEP80 on the basis of their size and amino-acid composition, as analysed by the method of Cornish-Bowden<sup>13</sup>. Two-dimensional electrophoresis was used to determine whether either of these known ribosomal proteins is the long extension.

S27 and S27a are well separated from other small subunit proteins in the gel system used to name ribosomal proteins<sup>14</sup>, but the protein pattern in these acid-urea gels could only be partially transferred to nitrocellulose. A provisional identification of rat CEP80 was nevertheless possible as the protein detected with CEP80-specific serum was located between and below proteins S28 and S27 (data not shown). This position is occupied by only one known ribosomal protein, S27a<sup>14,15</sup>. Rat ribosomal proteins have been examined in other two-dimensional electrophoresis systems, two of which use SDS-PAGE in the second dimension<sup>15</sup>. These protocols allow the reproducible transfer of proteins to nitrocellulose and, as shown in Fig. 2, our separations of rat 40S subunit proteins are comparable to published patterns<sup>15</sup>. Identification of CEP80 as 40S subunit protein 27a is based on the position of the immunodetected extension as well as its mobility relative to protein S27 in the two electrophoresis systems. S27a is the only small 40S

\* Present address: Department of Biology, Molecular and Cellular Biology Section, University of Alabama, Box 870344, Tuscaloosa, Alabama 35487-0344, USA.

subunit protein that has significant shift in relative mobility between the two first-dimension gel systems<sup>15</sup>. CEP80, like S27a, migrates farther than S27 in the low pH system, but not as far as S27 in high pH gels (Fig. 2). These properties identify the long ubiquitin extension as ribosomal protein S27a.

Comparisons of amino-acid contents suggested that rat S27 is the long extension protein, but two-dimensional electrophoresis of 40S subunit proteins in three gel systems identified rat S27a as CEP80. Given these results and the similarity in amino-acid composition of rat S27 and *Artemia* S27a, we conclude that rat S27a was previously misidentified. Chemical modification during isolation may have altered the electrophoretic mobility of the purified rat protein<sup>9</sup>, whereas the isolation of *Artemia* S27a directly from electrophoretic gels would avoid this problem<sup>11</sup>.

Identification of CEP80 as a previously recognized ribosomal protein does not prove that it has a ribosomal function. Co-isolation of the long extension protein with a single ribosomal

subunit reduces the possibility that the association is artefactual<sup>16</sup>, but subunit-specific adventitious binding has been observed previously<sup>17</sup>. CEP80 remains bound to the 40S subunit in salt solutions significantly above the 0.5 M concentration generally considered diagnostic for specific binding. Additional evidence for specificity was obtained by ion-exchange chromatography. Rabbit reticulocyte CEP80 elutes from DEAE columns with proteins that exactly match those of the 40S ribosomal subunit demonstrating that its association with the small subunit is independent of the isolation method (K.R., unpublished results). Further evidence for interaction between the long extension and ribosomes comes from *in vivo* studies of yeast strains lacking the gene for the yeast homologue of CEP80. These yeast grow slowly<sup>18</sup>, have a reduced ratio of small to large ribosomal subunits and inefficiently process the precursor for 18S ribosomal RNA<sup>19</sup>. We expect that a yeast small subunit protein will soon be identified as the 76 amino-acid yeast long-extension protein. Indeed, the deduced amino-acid

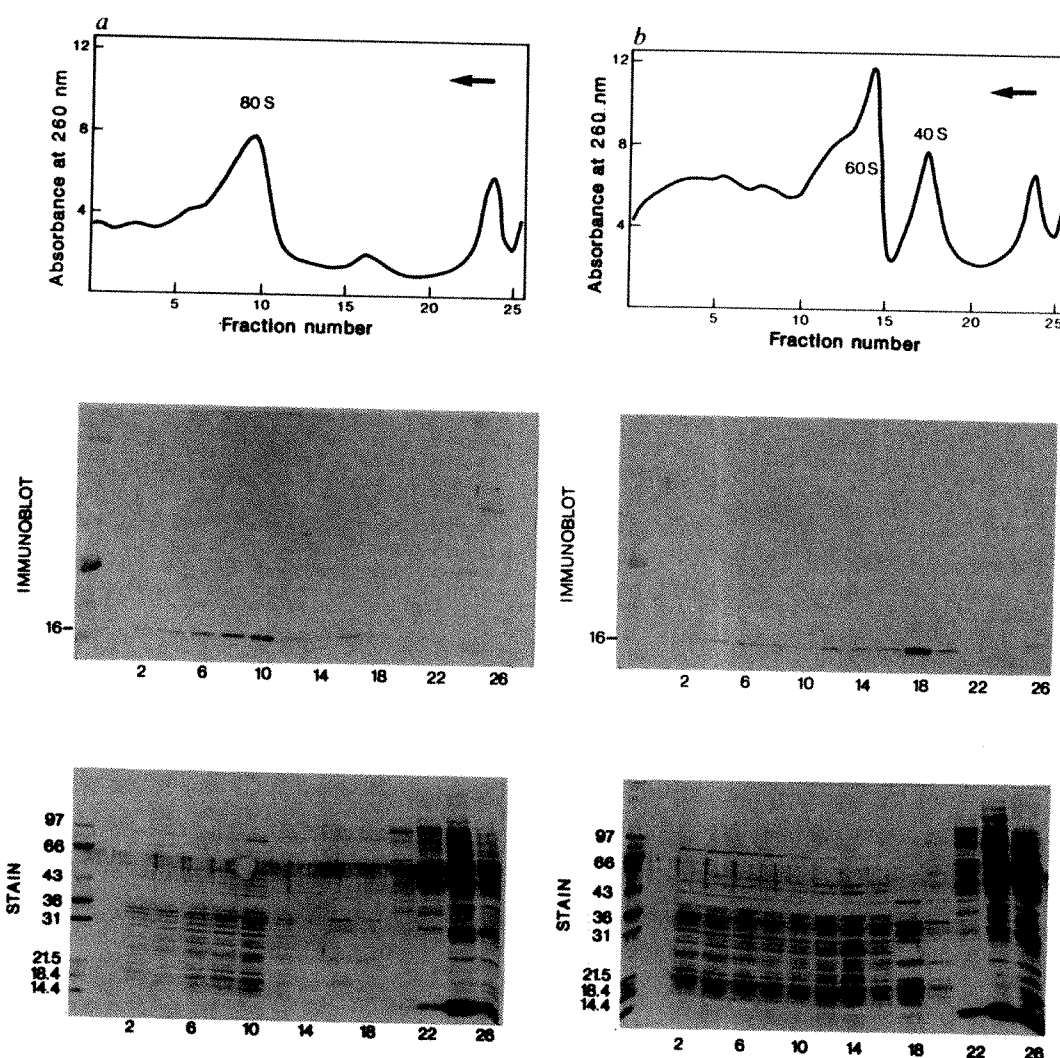

FIG. 1 Sedimentation of rabbit reticulocyte CEP80 in sucrose gradients. Resuspended polysomes were sedimented in low ionic strength buffer (a), or in high salt buffer to dissociate ribosomal subunits (b). Upper panels are profiles of absorption at 260 nm of gradients sedimented in the direction of the arrow. Middle panels are immunostained transfers of proteins from even-numbered fractions after separation by SDS-PAGE. Lower panels are transfers of identical gels stained with amido black. Relative molecular masses were estimated from prestained Rainbow markers (Amersham) on immunoblots and conventional markers<sup>8</sup> on stained blots and are shown on the left, n thousands.

METHODS. Reticulocyte lysate prepared from rabbits<sup>24</sup> was centrifuged for

2 h at 100,000g. Samples of the pellet, containing 40–60  $A_{260}$  units in 0.5 ml, were layered on to 11.5-ml linear gradients of 10–35% sucrose and centrifuged at 187,000g for 2.5 h. Aliquots of the 0.5 ml fractions were analysed by SDS-PAGE on 10–20% acrylamide gradient gels and electroblotted on to nitrocellulose<sup>8</sup>. Immunostaining (using extension protein-specific antiserum P7, goat-anti-rabbit peroxidase-coupled IgG and 4-chloro-1-naphthol) and protein staining were as previously described<sup>8</sup>. The sample and gradient in a were prepared in 50 mM Tris pH 7.8, 12.5 mM  $MgCl_2$ , 80 mM KCl, whereas the sample in b was prepared in the same buffer containing 880 mM KCl and analysed on a gradient containing 500 mM KCl.

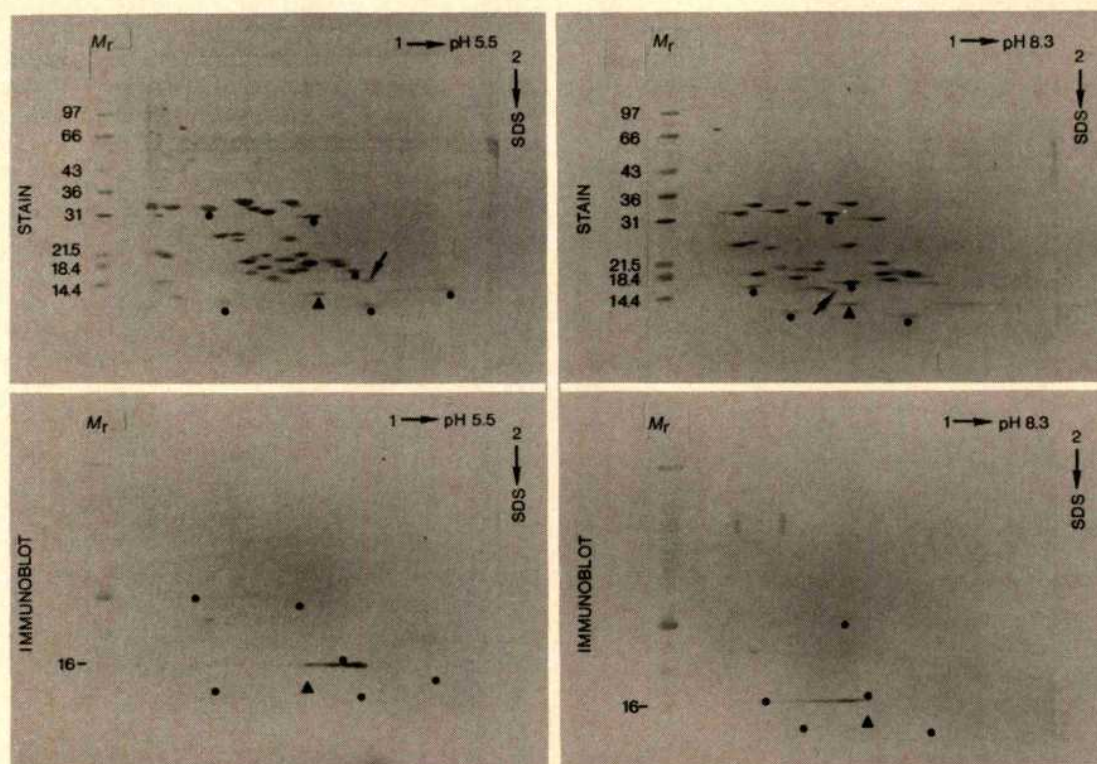

FIG. 2 Immuno-identification of the long ubiquitin extension. Identical nitrocellulose transfers of two-dimensional gels were amido-black stained or immunoblotted after reversible Ponceau S staining<sup>25</sup>. Arrows on the stained transfers indicate the position of the immunoreactive protein. The position of S27 is indicated by a triangle. The relative molecular mass ( $M_r$ ) markers used in Fig. 1 were added to the second-dimension gels (sizes in thousands). METHODS. 40S ribosomal proteins were prepared from the livers of Long-Evans rats as described<sup>15</sup>, and 80  $\mu$ g were separated on acid-urea/SDS

gels (left) or pH 8.3 Tris-borate/SDS gels (right)<sup>26</sup>. SDS-PAGE was performed as described<sup>8</sup>, except that the concentration of Tris in the separating gel was increased to 0.56 M to improve the resolution of small proteins<sup>27</sup>. Transfers were either stained with amido black (upper panels) or Ponceau S to locate individual proteins. After marking the positions of specific proteins on both blots (black dots), the Ponceau S transfers were de-stained and used for the immunodetection of CEP80 as in Fig. 1.

composition of the yeast long extension<sup>4</sup> is nearly identical to that determined for yeast small-subunit protein YS 24 (ref. 20), a protein that is similar in mobility to mammalian CEP80 upon acid-urea/SDS two-dimensional gel electrophoresis<sup>21</sup>.

Why do eukaryotic cells synthesize a ribosomal protein fused to ubiquitin? This novel gene arrangement may have a regulatory role as the translation product is cleaved<sup>8</sup>, and synthesis of the extension protein as a ubiquitin fusion product is not required for wild-type growth in yeast<sup>19</sup>. Degradation of misprocessed, misfolded or otherwise short-lived polypeptides is an important function of ubiquitin-mediated proteolysis<sup>22</sup>. We propose that the fusion gene provides a mechanism to maintain a fixed ratio between ubiquitin, necessary for degrading aberrant proteins, and ribosomes, a major source of aberrant proteins. By binding to ribosomes and its own mRNA, S27a could regulate its own translation and that of ubiquitin. This form of translational regulation has been shown to occur for *Escherichia coli* ribosomal protein operons<sup>23</sup>, but not for the monocistronic genes that encode eukaryotic ribosomal proteins. Although it remains to be seen whether our proposal is correct, conservation of this unusual gene arrangement among eukaryotes implies that there is an important physiological basis for co-synthesis of ubiquitin and a ribosomal protein. □

ANNOUNCING AN IMPORTANT EVENT IN SCIENCE PUBLISHING!

# THE MACMILLAN MOLECULAR BIOLOGY SERIES

General Editor: Dr C J Skidmore, University of Reading

MACMILLAN MOLECULAR BIOLOGY

## Genetic Elements in *Escherichia coli*

by Dr Peter Smith-Keary

Written for students of molecular genetics and molecular biology, the first volume in the series sets the scene by introducing aspects that provide the scientific background for the major technical advances of genetic engineering. Central topics such as replication, mapping, mutation, transposition and both general and site specific recombination are fully documented.

PB 0333 442687 £9.95 HC 0333 442679 £25.00

## Organelles

by Dr Mark Carroll

Aimed at second and third year undergraduate students following courses in biochemistry and cell biology, *Organelles* draws together the latest developments in our understanding of the ultrastructure and function of cell components. Each major cell organelle is the subject of one complete chapter, which ends with self-study questions to focus the reader on central concepts and principles. Throughout the book there are numerous micrographs and line illustrations.

PB 0333 44244X £9.95 HC 0333 442431 £25.00 (February 1989)

### Forthcoming titles include:

**What is a Gene?** by Dr C J Skidmore

**Protein Biosynthesis** by Dr R Jagus

**The Molecules of the Cytoskeleton** by Dr L Amos and Dr W B Amos

Code 355

## ORDER FORM

Paperback copies are available on inspection to lecturers in the UK where this may result in an adoption of 12 or more copies. If you would like an inspection copy please indicate in the space provided and return this form to: Inspection Copy Department, Macmillan Education, FREEPOST, Houndmills, Basingstoke, Hants RG21 2BR.

# Measuring the new superconductors

J. D. Doss

Faster, more straightforward methods are needed for testing the new high-temperature copper-oxide superconductors. A non-contact eddy-current characterization instrument particularly suitable for screening large numbers of samples will soon be on the market.

SEVENTY-EIGHT years ago in Leiden, the Netherlands, a small team headed by Heike Kamerlingh Onnes discovered superconductivity. The historic measurement on a column of frozen mercury was performed by Onnes's graduate student, Gilles Holst, who nulled a Wheatstone bridge in an attempt to measure a resistance that vanished below 4.2 K. Ever since that landmark measurement, the determination of d.c. resistance has remained the most common method for the characterization of superconductors. The Wheatstone bridge, of course, has now been replaced by sophisticated constant-current sources and microvoltmeters.

Even though d.c. resistance measurements are useful, the typical experimentalist requires additional measurement capabilities for superconductor characterization. Because zero voltage loss occurs only in static fields, other techniques are required to measure the small but finite losses found in the presence of alternating fields. Non-contact techniques are generally preferred (particularly in the study of superconducting thin films) because contacts tend to modify the superconductor surface.

## Magnetic phenomena

With the information available to them, it was quite natural that Onnes and his contemporaries should believe that a vanishing d.c. resistance was the most fundamental indicator of superconducting behaviour. (It is not.) The most definitive property of superconductivity was not discovered until 1933, when Walter Meissner and Robert Ochensfeld demonstrated that magnetic flux is expelled from a superconductor as it is cooled through its transition temperature. The discovery of near-perfect diamagnetism ( $\mathbf{B} = 0$ ) was the first clue that superconductivity is fundamentally a magnetic phenomenon<sup>1</sup>.

The significance of the Meissner-Ochensfeld experiment is not lost on those who are investigating the new family of copper-oxide superconductors. While candidate superconductors may be identified initially through a d.c. resistance measurement, true superconducting behaviour is proven only by demonstration of the Meissner effect. The measurement of magnetization ( $\mathbf{M}$ ) is also a routine procedure in the evaluation of superconductors. Much about the quality of a superconductor can be inferred from its

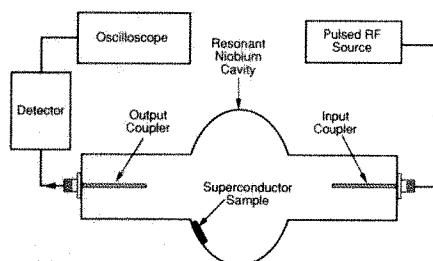

FIG. 1 The surface resistance of a superconducting sample may be determined by measuring its perturbing effect on the  $Q$  of a resonant cavity. The "decrement" method, used for measuring the high values of  $Q$  exhibited by superconducting cavities, is illustrated here.

susceptance ( $\chi$ ); indeed, the superconducting proportion of a multi-phase compound can be determined by measuring the flux expelled from a known volume of material. (Note:  $\chi = M/H$ ;  $\mathbf{B} = \mu_0[\mathbf{H} + \mathbf{M}]$  in SI units, while  $\mathbf{B} = \mathbf{H} + 4\pi\mathbf{M}$  in gaussian units.)

Despite the value of susceptometry, the measurement of flux expulsion is not the most convenient method for screening large numbers of samples, primarily due to cost and time constraints. The magnetic susceptibility of very small samples, such as films whose thickness is less than the London penetration depth ( $\lambda_L$ ), is also very difficult to measure, because they exhibit no significant expulsion of magnetic fields. Thin films are of considerable interest for electronic applications of the new high-temperature superconductors, but other techniques must be used to determine their quality.

## Surface resistance

Determining superconductor energy loss at frequencies ranging up to tens of GHz is important not only for classical radio frequency (r.f.) applications, but also for predicting the performance of superconductors in high-speed computer circuitry. A variety of techniques are employed to characterize superconductor loss at high frequencies, including several approaches where the sample is placed in some type of transmission line: subsequent perturbations are related to the sample's dissipation of energy<sup>2</sup>.

A very effective method for determining the microwave surface resistance ( $R_s$ ) of high-transition temperature (high- $T_c$ ) superconductors involves measuring the perturbation caused by placing the sample inside a resonant cavity. The cavity is first

calibrated by measuring the quality factor ( $Q$ ) of the empty cavity, which is inversely proportional to the resistance of its inner surface, and the  $Q$  of the "loaded" cavity using a sample of similar geometry with a known  $R_s$ , such as stainless steel. With this data, one may determine the surface resistance of a superconducting sample measured in the cavity<sup>3,4</sup>. For example, 3 GHz cavity perturbation measurements on bulk  $\text{Ti}_2\text{Ca}_2\text{Ba}_2\text{Cu}_2\text{O}_m$ ,  $\text{Bi}_2\text{CaSr}_2\text{Cu}_2\text{O}_x$ , and  $\text{YBa}_2\text{Cu}_3\text{O}_x$  yield  $R_s$  values ranging from  $10^{-4} \Omega$  to  $\sim 4 \times 10^{-3} \Omega$ , compared to  $\sim 10^{-6} \Omega$  for Nb (ref. 4).

Cryogenic copper cavities are useful in some instances, but superconducting cavities are generally preferred when higher sensitivity is required. The  $Q$  of non-superconducting cavities may be determined by standard bandwidth measurements, because these have relatively large bandwidths. ( $Q$  is equal to  $f/bw$ , where  $f$  is the resonant frequency, and  $bw$  is the bandwidth within the  $-3$  dB points.) When superconducting cavities are used, the direct determination of bandwidth is not always straightforward, because the  $Q$  of the empty cavity may exceed  $10^6$ . At a resonant frequency of 1 GHz, this implies a bandwidth of only 1 Hz, hardly a value one would wish to measure with a sweep-frequency generator. The higher  $Q$ s are measured by the "decrement" method to determine the fill (or decay) time ( $\tau$ ) of the cavity, which is driven from a pulsed r.f. source (Fig. 1). ( $Q = \pi f \tau = \omega \tau / 2$ , where  $f$  is the microwave frequency (usually near  $f_0$ ) used for the measurement<sup>5</sup>.) While resonant-cavity measurements are the preferred method for determining  $R_s$ , simpler non-contact methods may be used to screen large numbers of samples to identify those specimens which are worthy of more detailed studies.

## Eddy-current techniques

Precision "eddy-current" techniques have been used to determine the resistivity, transition temperature ( $T_c$ ), and penetration depth ( $\lambda_L$ ) of metallic and superconducting samples<sup>6-8</sup>. A modified eddy-current technique may also be used to characterize resistance losses in a qualitative manner, to determine  $T_c$  and the detailed structure of the superconducting phase transition<sup>9</sup>. As illustrated in Fig. 2, coupled inductors  $L_1$  and  $L_2$  may be used to induce r.f. currents in a superconductor

FIG. 2 Eddy-current analysis reveals energy losses below the critical transition temperature usually not apparent from d.c. resistance measurements. In d.c. measurements, a single thread-like superconducting path can "short" the contacts, effectively masking information about behaviour at lower temperatures. Two types of eddy-current oscillator circuits are shown.

sample. The induced current, a function of the sample's energy dissipation modifies not only the mutual inductance, but also the self-inductance of each coil. The inductive sensors are combined with capacitance ( $C_s$ ) to form a series-resonant circuit. The addition of a wide-band amplifier to close the loop yields an oscillator whose frequency is a function of sample energy dissipation (losses).

While the dual-coil system is less sensitive to microphonic noise, very effective systems can also be designed using a single sensor coil. In either case, oscillator frequency is plotted as a function of sample temperature to reveal details about energy losses, yielding information not available from d.c. resistance measurements at temperatures below  $T_c$  (ref. 10). While it is rarely a serious problem, eddy-current characterization does have a limited dynamic range. For extremely high or low values of sample resistivity, changes in resistance may not be sensed for a particular coil-sample configuration. Within limits, the dynamic range can be shifted to a more appropriate region by modifying the coupling between the sample and the sensor coil(s). Los Alamos National Laboratory has transferred its eddy-current technology to Lake Shore Cryotronics, Westerville, Ohio, which is preparing both single-sample and multiple-sample superconductor screening products for the market. □

## Quantitative aids

A top-loading microbalance, a micro-respirometer, a gaussmeter, and a range of pre-calibrated electrodes are a few of the latest measuring devices for the laboratory.

THE Micro-Oxymax **computerized metabolic computer** from Columbus Instruments measures oxygen consumption and  $\text{CO}_2$  product simultaneously in 10 chambers, varying in size from 100 ml to 10

Micro-Oxymax: the newest respirometer from Columbus Instruments.

litres (Reader Service No. 101). Columbus Instruments says the Micro-Oxymax can be used to measure the metabolism of insects, the proliferation of bacteria or moulds, and the oxygen uptake of tissue cultures and fermenters, with a sensitivity down to  $0.2 \mu\text{L}$ . Measurements can be performed in ambient temperature or in a temperature-controlled waterbath. The measurement intervals can be specified between 5 minutes and 24 hours. The Micro-Oxymax measures the volumes of  $\text{O}_2$  and  $\text{CO}_2$  consumed or produced by the sample under study, and monitors the temperature of the sample chamber. The system is controlled by an IBM-PC or compatible computer; data is saved and reports are generated automatically.

SLM Instruments, Inc. introduced a new **cation measuring spectrofluorometer** earlier this month for use in studies involving intracellular calcium probes such as Fura-2 and Indo-1, and other multiple-wavelength fluorescent probes (Reader Service No. 102). The company's computerized model DMX-1000 Multiparameter Cation Measuring Spectrofluorometer is a combination of a high-speed scanning spectrofluorometer with a light-chopped excitation system. The spectrofluorometer's T-Optics configuration especially suits it for measuring multiple-excitation wavelengths, but it can also be

used for ratiometric measurements and polarization studies. Because of the modular nature of the model DMX-1000, polarizers, filters and other accessories can be installed as needed. Available accessories include a stopped-flow accessory, and a programmable cell changer that can handle four samples.

Genzyme Corporation has launched three new enzyme-based kits for **oligosaccharide analysis** (Reader Service No. 103). Genzyme's UnLinkit-N, AnaLink-N and EndoLink kits can be used to release asparagine-linked oligosaccharides from glycoproteins and glycopeptides, for subsequent analysis using HPLC. Genzyme's kits can be used with the Waters range of columns designed for analysing released oligosaccharides.

### High $T_c$ tech

The French company Drusch has a **nuclear magnetic resonance gaussmeter** for use in solid-state or nuclear physics laboratories (Reader Service No. 104).

The Drusch model RMN 2 nuclear magnetic resonance gaussmeter.

Drusch says the model RMN 2 gaussmeter is simple to operate: the user selects a probe appropriate for the expected field strength, places the probe in the field, and turns on the instrument. Probe alignment is not critical to the measurement, and the probe can be located up to 160 feet away from the readout. The RMN 2 is based on the measurement of the gyromagnetic ratio of protons as the input frequency is swept through the range of interest. Drusch says its gaussmeter can measure any field between 20 mT and 9 T with a precision of  $5 \times 10^{-3}$  mT, and a relative precision of at least  $5 \times 10^{-4}$  mT. The model RMN 2 can also automatically track a varying magnetic field at speeds of up to 10 mT per second.

Mettler's new modular model TA4000 **thermal analysis system** has an extended differential scanning calorimetry range of

-170 to +750 °C, and displays curves in real-time when connected to a PC (*Reader Service No. 105*). The system offers one-key automatic analysis for differential scanning calorimetry, thermomechanical analysis and thermogravimetric analysis. All test programs are permanently stored in the system processor, which can output a complete analysis record to a printer. The system's optional TA72 software allows the model TA4000 to work with an IBM AT or PS/2 computer for on-screen curve plotting, kinetic evaluations, and test data storage.

### Balancing acts

The first **toploading microbalance** is new from Sartorius Instruments (*Reader Service No. 106*). Sartorius's model M3P is sensitive to 1 µg, and has three sensitivity ranges and a maximum capacity of 3 g. Unlike conventional microbalances,

Top-loading microbalance from Sartorius.

Sartorius's balance has no large weighing chamber with mechanical devices to extend and retract the weighing pan. Users can deposit and retrieve samples quickly, with no lockdown procedures to follow or doors to open and close. The microbalance calibrates automatically, and has built-in programs for data processing. The low-profile, compact model M3P has an RS232 interface for connection to a computer for saving or importing data to other programs.

The Japanese company A & D Company, Ltd has an **analytical balance** that comes with a wireless remote control and a vibrating spoon (*Reader Service No. 107*). The company's balance comes in two models: the FR-200 weighs samples up to 210 g in 0.1 mg increments, and the FR-300 handles up to 310 g with the same precision. The balance has a percentage and counting function, and can be used to weigh in grams, carats, pennyweights, decimal ounces, troy ounces, grain units, tolas, taels and mommes. A & D's analytical balance can be calibrated with the touch of a button, and has an interval data output feature that sends weighing data to a computer at set intervals. The balance

controls the vibrating spoon at frequencies between 110 Hz and 230 Hz.

The CP Instrument Company has a **pocket-size digital scale** that measures just 142 × 87 × 15 mm (*Reader Service No. 108*). The top-loading balance is ideal for use in the field, and saves space in the laboratory. Its weighing capabilities belie its small size: the scale measures up to

CP Instrument Co.'s balance fits in a pocket.

500 g in 1-g increments, and up to 1 kg with a precision of 2 g. The balance is described in CP Instrument Company's 160-page catalogue, which has ten pages devoted to balances.

### Spectral studies

Minolta has a compact, **portable spectrophotometer** for colourimetric studies (*Reader Service No. 109*). The model CM-1000 has a flip-up LCD screen, much like a lap-top computer, and a hand-held spectral sensor which measures wavelengths between 400 and 700 nm using a 40-segment silicon diode array and a spectral filter array. The unit has a built-in printer, an RS-232 interface, and a 3.5-inch floppy disk drive. Statistical software allows spectral and colourimetric data to be displayed graphically, in two and three dimensions.

The model ELS-800 **electrophoretic light-scattering spectrophotometer** from Otsuka Electronics was developed for the determination of the surface charges of fine particles and electrophoretic polymers (*Reader Service No. 110*). The system can be used to study protein degeneration, the interaction between proteins and surfactants, the dispersion and aggregation of liposomes and vesicles, and the properties of surfactants and micelles. The model ELS-800 uses the optics of the Heterodyne dynamic scattering method to yield measurements of the zeta potential and electric mobility distribution based on the laser Doppler electrophoretic method. The system's correlator software employs a fast Fourier transform.

### Image analysis

The BioVision personal **microscope workstation** from Perceptics puts the power of an Apple Macintosh II with a high-resolution colour monitor to work with an optical microscope, an image sensor, a frame grabber, and TCL-Image biological software designed for biomedical research (*Reader Service No. 111*). Perceptics designed the workstation for entry-level image analysis: the company says the mouse, icons, windows and pull-down menus of the Macintosh reduce learning time and simplify operation. The system's frame grabber provides real-time image capture with 256 gray levels. The workstation's TCL-Image software performs arithmetic, linear and non-linear neighbourhood, binary, and morphological operations, along with distance, image and Fourier transformations. Users can also append their own image processing functions, and develop application programs using the existing library functions.

Digithurst Ltd offers a range of **low-cost colour image analysis systems** at prices

### ADVERTISEMENTS

#### BIANORM EQUILIBRIUM DIALYSIS SYSTEM

The gentlest method to quantify the binding parameters and thermodynamic data between ligands and biopolymers. Results come closest to the actual values. Sample volume from 0.2 ml to 5.0 ml. Up to 20 experiments in parallel.

comparable to monochrome systems (*Reader Service No. 112*). Digithurst's microcomputer-based MicroScale IC for entry-level applications and MicroScale IIC for more advanced studies range in price from under £1,000 to £12,000 (UK). Both packages offer object measurement, including area, perimeter, position, diameter, orientation and volume, and whole-field measurement of area, perimeter, and average intensity. Because every pixel within an image is quantified in

Low-cost image analysis from Digithurst.

terms of its colour content, not just its intensity (as in a monochrome system), the MicroScale systems can cope with extremely complex colour combinations. Thresholds of colour are set manually with the MicroScale IC, and automatically or manually with the MicroScale IIC.

## Electrochemical sensors

Diamond General's Chemical Microsensor II can be operated simultaneously in the amperometric, potentiometric and thermal sensing modes (*Reader Service No. 113*). The **ion electrode** can determine the concentrations of chemical species such as pH, CO, PO, and PH. The compact Chemical Microsensor II fits easily on

Measure most any ion with the Chemical Microsensor II.

the lab bench, and its battery pack allows it to be carried into the field for performing on-site measurements.

Beckman Instruments has six new **calomel combination electrodes** designed especially for use in biologicals and other silver-sensitive solutions, including Tris buffers, enzyme preparations, tissue culture media, sulfides, bromides and iodides (*Reader Service No. 114*). The Beckman FUTURA Plus electrodes are offered in six styles: with glass bodies measuring 12 mm × 130 mm, 10 mm × 195 mm, 5 mm

Beckman's array of pre-calibrated electrodes.

× 225 mm, and 5 mm × 178 mm; and with epoxy bodies measuring 12 mm × 130 mm and 7 mm × 225 mm. The electrodes can be used at temperatures of between 23 and 140 °F. Each electrode comes preconditioned in its own Performance Pac vial, and can be used right out of the box, with no soaking.

## Pipette products

Rudolf Brand GmbH has two new **multi-channel pipettes** which can dispense eight or twelve volumes of liquid between 5 µl and 200 µl, at one shot (*Reader Service No. 115*). The Transferpette-8 and Transferpette-12 are ergonomically shaped for comfort, and the volume-setting, pipetting and tip-ejection functions are separated to avoid errors. Brand says the pipettes can be used to fill a large number of microtitre plates without giving the user a cramped hand, because the user's thumb always remains in a natural position. Both pipettes weigh roughly 150 g, and a digital display shows the set volume. The dosing portion of the pipettes can be screwed off for autoclaving. Brand says the Transfer-

Eight- or twelve-channel pipetting from Brand. pipettes function with errors in accuracy of less than 1.5 per cent of the nominal volume.

Flow Laboratories recently launched a cordless, **rechargeable pipetting controller**

designed for use with pipettes ranging in size from 0.1 ml to 100 ml (*Reader Service No. 116*). Named the Pipetus Akku, the controller weighs 180 g, operates for up to five hours on one charge. When set at minimum power, operation can be extended to 15 hours without recharging. Flow's controller was designed for cell culture media preparation, and comes

Flow's cordless, rechargeable pipette controller.

complete with a recharging unit for £175 (UK). The Pipetus Akku features a 0.2 mm hydrophobic PTFE membrane filter with luerlock connections for air filtration. With normal use, Flow says the unit is maintenance-free, except for periodic filter replacement. Two safety features are included: a safety valve prevents flooding of liquid into the controller, and the entire controller can withstand fumigation with formaldehyde. Dispensing and filling are controlled by separate buttons.

Hamilton's Microlab 1000 **diluter dispenser** has been designed to accommodate liquid volumes of between 1 µl and 25 ml (*Reader Service No. 117*). Users can program the Microlab 1000 with up to 5

The new programmable diluter/dispenser from Hamilton boasts 50 protocols.

protocols by answering a series of yes-or-no questions displayed on the instrument's LED. The diluter/dispenser automatically calculates optimum syringe size, valve size and syringe speed for each application.

## Instrumentation Physicist

Daresbury Laboratory operates major national facilities for fundamental and applied research in a wide range of sciences.

### • The Job

We have a vacancy for an Instrumentation Physicist to join a multi-disciplinary research support group with a primary interest in experimental methods in non-crystalline diffraction using synchrotron radiation and related techniques. The successful candidate will be expected to make a major contribution towards the development of specialised instrumentation vital to the research projects of visiting and in-house users embracing a wide range of physical, chemical and biological applications.

The post holder will be expected to solve instrumentation problems which could arise in the control and monitoring of synchrotron beams, X-ray optics, preparation of samples, the dynamics of sample environment, and, in particular, the application of high resolution high rate X-ray imaging detectors.

The post entails working with staff at all levels in varied disciplines and demands qualities of resourcefulness and adaptability.

### • Qualifications and Experience:

Applicants should have a relevant degree or equivalent qualifications. Candidates with a 1st or 2nd class honours degree should have 2 years post-graduate research and development experience. Candidates with other qualifications should have 5 years appropriate experience.

### • Pay:

The appointment will be made at the Higher Scientific Officer grade within a salary range of £10,026 to £13,460 per annum according to qualifications and experience. Further increments are available depending on performance. A non-contributory superannuation scheme and a flexible working hours scheme are in operation at the Laboratory.

**CLOSING DATE:** 14th April, 1989

Application forms may be obtained, quoting reference DL102, from: The Personnel Officer, Daresbury Laboratory, Science and Engineering Research Council, Daresbury, Warrington, Cheshire WA4 4AD.

Telephone (0925) 803467  
(24 hour answering service). (8871)A

**Daresbury**  
SCIENCE & ENGINEERING  
RESEARCH COUNCIL

**ROYAL PERTH  
HOSPITAL**

*'An Equal Opportunity Employer'*

## SENIOR RESEARCH OFFICER

**NH & MRC PROGRAMME GRANT  
Department of Clinical Immunology**

A Senior Research Officer is required to contribute in the area of molecular biology, immunogenetics, receptor biochemistry and cellular immunology. The successful applicant would join a team investigating the immunogenetics of autoimmune disease, with particular attention to the acetylcholine receptor and MHC Class III genes.

Techniques involve monoclonal, antibodies, Southern blotting, DNA sequencing and pulsed field gel electrophoresis. Experience in protein biochemistry would be an advantage.

Appointment will be made initially until the end of 1990 but may be extended to at least four years. Salary would be according to NH & MRC scales, commencing at \$30,737 after six years post Doctoral experience. Supplements may be negotiated.

Written applications addressed to Dr R.L. Dawkins, Department of Clinical Immunology, Royal Perth Hospital, Box X2213, GPO, Perth, WA — Applications should include names and addresses of two professional referees.

**CLOSING DATE:** Friday, 14 April 1989.

(W6006)A

## SEISMOLOGY OR MINERAL PHYSICS UNIVERSITY OF MICHIGAN

The Department of Geological Sciences invites applications for a new tenure-track position at the Assistant Professor level, or in exceptional cases at a higher level, to begin in January 1990 or later. We seek applicants with broad research interests in either seismology or mineral physics for this single open position. We interpret mineral physics broadly, to include both theory and experiment, dealing with both solids and melts. This is an incremental position which augments our existing faculty in these areas. Teaching responsibilities will be at both the undergraduate and graduate level, with occasional participation in introductory earth science courses. A PhD is required. Interested persons should send a résumé, names of five persons from whom the Department may request letters of recommendation, and a brief statement of research interests, to **Prof. Rob Van der Voo, Chairman Search Committee, Department of Geological Sciences, the University of Michigan, Ann Arbor, MI. 48109-1063.** The search will close August 1, 1989, but later applications may be considered. The University of Michigan is an affirmative-action, equal-opportunity employer. (NW3525)A

## DEPARTMENT OF BIOLOGY, QUEEN'S UNIVERSITY KINGSTON, ONTARIO, CANADA

The Department of Biology at Queen's University invites applications for a tenure-track position in the area of **ANIMAL PHYSIOLOGY**. Preference will be given to vertebrate physiologists whose research work involves physiological approaches to environmental or ecological questions, but researchers in all areas are encouraged to apply.

**QUALIFICATIONS:** The successful candidate should be an enthusiastic and competent teacher and will be expected to develop a vigorous research program. Qualifications include a Ph.D. degree and published evidence of excellent research ability.

**EXPECTED DATE OF APPOINTMENT:** This appointment can be effective July 1, 1989 (or as negotiated) and is expected to be at the rank of assistant professor with salary commensurate with qualifications.

**APPLICATION DEADLINE:** The application deadline is **May 15, 1989** or until a suitable candidate is selected. Applications should include a curriculum vitae and a statement of future research interests. Arrangements should also be made to have three letters of reference sent to: **Dr. D. T. Dennis, Head, Department of Biology, Queen's University, Kingston, Ontario, Canada K7L 3N6.**

*In accordance with Canadian Immigration requirements, this advertisement is directed to Canadian citizens and permanent residents.*

Candidates of either sex are equally encouraged to apply. Queen's University is willing to help the spouse of a new appointee to seek employment. (NW3521)A

**British Postgraduate Medical Federation**  
UNIVERSITY OF LONDON

## **Research Co-ordinator Science Planning Unit**

**Salary circa  
£15,000 per annum**

This large Postgraduate Medical School which includes the Institutes of Cancer Research, Child Health, Dental Surgery, Neurology, Ophthalmology and Psychiatry, and the National Heart and Lung and Hunterian Institutes, is establishing a new science Planning Unit to assist in the development and implementation of an academic plan.

The Research Co-ordinator, a graduate preferably with experience in data handling/computing, will be responsible for the day to day running of the project, maintaining close links with Institute staff and the Regional Deans in Medicine and Dentistry.

Further information and application forms are available from Jane M. Jones, Federation Secretary, BPMF, 33 Millman Street, London WC1N 3EJ (Telephone 01-831 6222) to whom applications should be forwarded by 20 April 1989.

(8847)A

## **SYSTEMS NEUROSCIENCE, CELLULAR NEUROSCIENCE, MOLECULAR NEUROSCIENCE; FACULTY POSITIONS DEPARTMENT OF NEUROBIOLOGY AND BEHAVIOR —SUNY STONY BROOK:**

The Department of Neurobiology and Behavior of SUNY Stony Brook is continuing its search for candidates for tenure-track, state-funded positions beginning as early as academic year 1989/90. The Department, which currently consists of 15 members, is undergoing significant redevelopment, and has the resources to grow to 20 members within the next 5 years. Presently available positions are at the Assistant Professor level although an appointment at the rank of associate Professor could be considered. Rank and competitive salaries will be commensurate with qualifications. All applicants should have a minimum of 2 years of postdoctoral experience. Candidates will be expected to develop a vigorous independent research program, and as such ample space and start-up funds will be provided.

Applicants should submit a curriculum vitae, statement of research interests, and names and addresses of three references to: **Dr. Lorne Mendell, Chairman, Department of Neurobiology and Behavior, SUNY Stony Brook, Stony Brook, NY 11794-5230.** SUNY Stony Brook is an affirmative action/equal opportunity educator and employer. AK 60.

(NW3516)A

**AFRC INSTITUTE FOR ANIMAL HEALTH**  
Compton, Newbury, Berkshire. RG16 0NN

## **A Head of Division is required for Immunology and Pathology**

Following a major restructuring of the Institute two major divisions: Molecular Biology, and Immunology and Pathology and two smaller divisions: Environmental Science, and Epidemiology, have been formed. We are seeking to appoint a Head of Division of Immunology and Pathology.

The post will be located at Compton but the successful applicant will be expected to manage an integrated programme across two major sites at Compton and Pirbright and the Neuropathogenesis Unit in Edinburgh. Opportunities exist to work on a number of endemic and exotic diseases of farm animals and to develop fundamental and applied programmes. The Head of Division will plan financial provision, control budgets, encourage collaborative links both within the UK and overseas and take an active role in the management of the Institute.

The successful candidate will have the opportunity to introduce and develop new research topics and appoint to a number of new posts. He/she will be responsible to the Director of Research Professor F. J. Bourne.

Applicants will have a higher degree and broad experience in modern immunological techniques, distinction in a relevant area of immunological research and an ability to manage scientific personnel.

The appointment will be at Unified Grade 5 with a salary on the scale £28,170-£31,602 with opportunity for further, performance related increments to £36,786. There is a non-contributory superannuation scheme.

Application form and further details are available from the **Personnel Officer, AFRC Institute for Animal Health, Compton, Berks, RG16 0NN.**

Closing date: 23 April 1989.

(8861)A

## **ANIMAL BIOTECHNOLOGY CAMBRIDGE LTD SENIOR MOLECULAR BIOLOGIST**

ABC Ltd is a rapidly expanding company in the forefront of the development of advanced transgenesis for the Pharmaceutical, Food and Livestock Industries. We have extensive in-house expertise in animal embryology, *in vitro* culture, stem cell technology and micro-manipulation.

We are looking for an accomplished Molecular Biologist with commercial awareness, to take responsibility for all molecular aspects of our programme and to participate in the development of contracts with our clients.

The successful candidate will have experience in recombinant DNA technology, mammalian gene cloning, and tissue culture. He or she will be responsible for preparing research proposals, setting up projects and managing them. In return we offer a competitive salary and fringe benefits, and the opportunity to work with a well-funded and dedicated team in a stimulating R&D environment.

*Please send your application, including CV and detailed description of previous relevant experience to:*

**Dr Martin Evans**

**Director of Transgenesis**

**Animal Biotechnology Cambridge Ltd  
Animal Research Station**

**307 Huntingdon Road, Cambridge CB3 0JQ**

**Telephone: (0223) 277222 (8860)A**

The security of staple food supplies and incomes in rural African communities is threatened by the presence of the Larger Grain Borer (LGB) insect. Recently introduced by accident into Africa from Central America, it is a highly destructive pest which causes serious losses of maize and cassava in traditional farm stores.

An ODA funded project will carry out work which is designed to obtain a better understanding of the ecology of the LGB and to develop integrated pest management strategies, which are appropriate in the threatened regions of Africa.

## **Entomologist (4 Posts)**

The posts require individuals to work as a member of a multi-disciplinary project team, together with staff of the national research institutes, in identifying and carrying out the work programme. You will also be expected to monitor and control budgets for local project expenditure and to provide a UK based Project Manager with regular reports of technical progress.

### **POSTS ONE and TWO MEXICO**

These appointments are for 2 years from June 1989. The responsibilities of the posts are to carry out a pheromone trapping survey, to determine the distribution of LGB in different regions of Mexico, to assess loss levels sustained by farmers storing maize, to investigate the source of infestation of maize by LGB and to determine the interaction between pest populations in stores and populations of the insect in the wider environment.

Additionally, you will investigate the potential for biological control of the pest in Africa by a specific natural enemy, study the relationship between LGB and other pests of stored maize, assist in identifying aspects of farming and storage systems which may influence the pest status and contribute to the development of sustainable, cost-effective strategies for the control of LGB in Africa.

### **POST THREE KENYA**

A 3 year appointment from June 1989. The responsibilities of this post are to establish a pheromone trapping system which will allow the continued monitoring of changes in the pest's distribution within Kenya, to assess loss levels sustained by farmers during storage, to investigate the source of infestation by LGB and to determine the interaction between pest populations in stores and populations of the insect in the wider environment.

In addition, you will investigate the relationship between LGB, other main pests of stored crops and natural enemies of storage pests which occur in these environments. You will identify and test technologies which can be used at farm level and which will help to reduce losses caused by LGB while recommending sustainable, cost-effective control strategies which can be rapidly implemented.

### **POST FOUR UK (Operating in Kenya/Togo)**

A 3 year appointment from June 1989. Although this post is based in the UK (Slough), you will make frequent trips to Kenya and to Togo in order to work with local research staff. Each trip will depend on specific programme needs, however, you can expect to spend several months overseas each time.

Your responsibility will be to establish and help operate a pheromone trapping system which will allow the continued monitoring of changes in the pest's distribution within Togo and investigate the source of infestation. In addition, you will determine the interaction between populations of the pest on the maize and cassava crops and the interaction between populations of the insect in food stores and those in the wider environment. You will investigate the relationship between LGB and other pests, investigate the bionomics of LGB populations infesting cassava and develop control methods for the protection of dried cassava against attack by the pest.

### **QUALIFICATIONS**

For all posts, applicants should be British Citizens with a postgraduate qualification in entomology or a closely related subject and at least 2 years' experience in a relevant field of work overseas. Ideally, you will have worked with insect pests of stored food grains and you will have been involved in the design and conduct of field and laboratory experiments in this field. For posts one and two, working knowledge of Spanish will be an advantage. For posts three and four, working knowledge of French will be an advantage.

### **TERMS OF APPOINTMENT**

All posts are on contract to the British Government and on loan to the appropriate overseas Government with a UK taxable salary commensurate with age, qualifications and experience. Benefits include tax free overseas allowances, children's education allowances, free accommodation and passages.

For details and application form, quoting the job title and appropriate ref. to: Appointments Officer, Overseas Development Administration AH220, Abercrombie House, Eaglesham Road, EAST KILBRIDE, Glasgow G85 8EA. Or tel. 03552 41199. Ext. 3533.

Posts one and two Ref. AH369/MN/N. Posts three and four Ref. AH369/DES/N.

# OVERSEAS DEVELOPMENT

BRITAIN HELPING NATIONS TO HELP THEMSELVES

(8835)A

INTERNATIONAL  
TRYPANOTOLERANCE  
CENTRE

**DIRECTOR**

The Governing Council invites applications for the post of Director of ITC.

ITC is an independent international research Institute committed to the management of trypanotolerance in cattle as a resource for the benefit of livestock owners in the tsetse-infested humid tropics of West and Central Africa. To this end, research programmes have been initiated in production, nutrition including pasture development, trypanosomiasis, helminthiasis, tsetse entomology and genetic improvement. The programmes operate on station and in the surrounding villages with the co-operation of local livestock owners.

Collaborative programmes are in operation with the International Laboratory for Research on Animal Diseases (ILRAD), the International Livestock Center for Africa (ILCA), L'Institut Senegalais de Recherches Agricoles (ISRA), the Overseas Development Administration (ODA) of the British Government, the Centre de Recherches sur les Trypanosomoses Animales (CRTA) and, more recently, with laboratories in Europe and America on a genetic improvement programme which includes both standard breeding and selection and genetic mapping with the aim of identifying the gene or genes responsible for Trypanotolerance.

ITC has three main stations, one near the coast, where the headquarters and main laboratories are located, and two inland, connected by good roads and radio telephone. There are 12 internationally recruited staff and 10 Gambian veterinary and agricultural scientists. They are presently supported by a staff of over 100 and several hundred agricultural workers recruited from the villages. It is intended in the future to extend the regional links with adjoining countries by the establishment of further jointly agreed activities.

ITC was established by Act of The Gambia Parliament 1982. The primary role of the Director will be the co-ordination of the scientific activities of the Centre to enact its aims as laid down in the Act.

Applicants for the Directorship should have a strong scientific background, as well as field experience and a personal interest in cattle. The Director will need to be highly motivated towards the improvement in the quality of village life to which end the research is directed. A working knowledge of English and French is essential. Applicants should hold a Ph.D. or equivalent and have a minimum of ten years experience in research and/or livestock development in tropical Africa, with some experience in leading multidisciplinary teams.

Short-listed candidates will be expected to travel to The Gambia where the final selection for Director will be made. Salary will be by agreement but within internationally accepted scales and according to experience and qualifications.

Further particulars may be obtained from and applications should be made to the office of the Chairman of ITC Council, Professor A.J.S. Davies at the following address: **The Institute of Cancer Research, The Haddow Laboratories, 15 Cotswold Road, Belmont, Sutton, Surrey SM2 5NG, UK. Fax: 01-642 9598.** (8870)A

**UNIVERSITY OF OXFORD  
MEDICAL RESEARCH COUNCIL  
ANATOMICAL NEUROPHARMACOLOGY UNIT  
ELECTROPHYSIOLOGIST**

The Unit is looking for a young electrophysiologist to join an active group working on the microcircuitry of cerebral cortex, using techniques of intracellular recording *in vivo* and *in vitro* combined with light and electron microscopy, immunochemistry, and computer modelling. The successful applicant will find it difficult not to get involved in most, if not all, of these areas. A basic grounding in electrophysiology is important, but most relevant skills will be developed on site. In short, a golden opportunity for the highly-motivated to expand their horizons. The post grade is MRC non-clinical scientific staff (grade 2, short term). Remuneration on the scale for university non-clinical academic staff up to a maximum of £14,500. Tenable for up to 3 years.

The postholder will work with Dr. Kevan A.C. Martin, (tel: 0865 275184), from whom further particulars could be obtained. Applications (CV and names of two referees) to **Prof. A.D. Smith, MRC Anatomical Neuropharmacology Unit, Department of Pharmacology, South Parks Road, Oxford, OX1 3QT. (FAX: 0865 275161).** Closing date 31 May, 1989.

Equal opportunity employer

(8855)A

**UNIVERSITY  
of GUELPH**

**DEAN,  
ONTARIO AGRICULTURAL COLLEGE**

The University of Guelph invites applications and nominations for the position of Dean of the Ontario Agricultural College. The appointment will commence on July 1, 1990.

The University of Guelph has a special responsibility within the Ontario University system to serve agriculture in the broadest sense. The University is committed to a leadership position in education, research and extension related to the use of the components of the agriculture and food system, whether these be physical, financial or human. We have a major concern regarding the impact of resource use on our environment and on society in general.

One of seven Colleges in the University, the Ontario Agricultural College offers a wide range of undergraduate, graduate and research programs in support of agriculture and has a major commitment to international activities. The College has approximately 180 faculty members in nine academic departments; Agricultural Economics and Business, Animal and Poultry Science, Crop Science, Environmental Biology, Food Science, Horticultural Science, Land Resource Science, Rural Extension Studies, and Landscape Architecture. The College currently enrolls approximately 1,300 students in its undergraduate and diploma programs and 460 students in its M.Sc., M.Agr., M.L.A. and Ph.D. graduate programs. The total annual research budget is in excess of \$22 million.

Applicants should have a proven record of leadership and achievement in education and research and a broad understanding of agriculture as it relates to universities, industry, government and society at large. The appointment as Dean will be for a five year term, renewable for an additional five years, and will include a tenured faculty appointment in an appropriate department. Applications and nominations should be submitted by May 15, 1989 to **Dr. J. R. MacDonald, Vice-President, Academic, University of Guelph, Guelph, Ontario, N1G 2W1.**

In accordance with Canadian Immigration requirements, priority will be given to Canadian citizens and permanent residents.

*The University of Guelph is committed to Employment Equity. (NW3513)A*

**Operations Support  
Scientist**

The Synchrotron Radiation Source (SRS) at Daresbury is a national research facility providing high brilliance photon beams at all energies from infra-red to hard X-ray at many different experimental stations.

The Laboratory has an international reputation and is used by industrial and academic scientists from this country and abroad for wide ranging research, including the areas of biological and materials science and surface studies.

The Operations Support Team is responsible for continuous operation of the three electron accelerators which make up the SRS and the provision of front line support for users working on beam lines and experimental stations.

We have a vacancy for an Operations Support Scientist to work on shift as a member of this team, specialising in one or more areas of the experimental programme.

This is a challenging job requiring experience in experimental research work or instrumentation relevant to synchrotron radiation. Practical ability with complex experimental, detector and computer systems is an important requirement for this post.

Minimum academic qualifications of a degree HNC/HND or equivalent are required.

The appointment will be made at Scientific Officer or Higher Scientific Officer level with salary in the range £8,574 to £13,460 depending on qualifications and experience. Further increments are available depending on performance. The Superannuation Scheme is non-contributory.

If you have relevant scientific and technical expertise and you would like to work at a large research facility supporting a varied and expanding research programme, then contact Paul Quinn on 0925 603261 for full details.

Application forms are available from the Personnel Officer, Daresbury Laboratory, Warrington, Cheshire WA4 4AD. Telephone: 0925 603467 (24 hour answering service) quoting reference DL/103.

CLOSING DATE: 13th April 1989.

## UNIVERSITY OF LIVERPOOL

### Leverhulme Centre for Innovative Catalysis

#### University of Dundee

#### Catalysis Research Laboratory

#### Controlled Sulphur Poisoning of Heterogeneous Catalysts

Applications are invited for the post of postdoctoral Senior Research Assistant/Research Associate tenable for up to three years from October 1989. This project concerns the modification of catalytic selectivity by the controlled addition of poisons at levels below those required for total loss of catalytic activity. The project involves two Universities (Liverpool and Dundee), and is sponsored by ICI Chemicals and Polymers Ltd. It is anticipated that the appointee will spend a significant portion of time at each research centre. Techniques of interest include surface analysis and microreactor studies at Liverpool, infrared and Raman spectroscopy at Dundee and catalyst preparation at ICI Chemicals & Polymers Ltd. The appointee will work closely with Dr Graham Hutchings (Liverpool) and Professor Colin Rochester (Dundee) and also maintain close contact with the Catalyst Group, ICI Chemicals & Polymers at Billingham. Informal enquiries may be made to Dr Hutchings, tel. 051-794 3585.

Initial salary within the range £9,865-£10,460 per annum.

Applications, together with the names of three referees, should be received not later than 15th May 1989, by **The Director of Staffing Services (AS), The University, PO Box 147, Liverpool, L69 3BX**, from whom further particulars may be obtained.

## RESEARCH FELLOW Aquatic Ecology/Toxicology

\$A31,003-\$A45,177

DIVISION OF WATER RESOURCES

GRIFFITH, NSW, AUSTRALIA.

**GENERAL:** The Division's research aims to provide public authorities and the private sector with improved methods for the definition, use and management of Australia's water resources.

The Division's 230 staff are located in Laboratories at Canberra, Perth, Griffith and Adelaide.

One of the programs in the Griffith Laboratory is concerned with the ecology and management of surface water. The program has several projects on water pollution, including degradation of water quality by growth of algae and associated micro-organisms. A close association is maintained with the Murray-Darling Freshwater Research Centre at Albury-Wodonga.

Griffith is situated approximately 400km north of Melbourne and 800km west of Sydney, and has a population of about 15,000. Educational and sporting facilities are excellent.

**THE JOB:** The appointee will complement an existing team working on odoriferous compounds of biological origin, and extend it into a study of toxins in water supplies. Aspects of study could include the eco-physiology of toxin production, development of biological/chemical assay methods; and investigation of options for dealing with the problem, either by modifying the aquatic environment or by conventional water treatment.

The Griffith laboratory is well equipped for chemical analysis (including closed loop stripping, GC-MSD; HPLC; ion chromatography, radioisotope area and autoanalysers). Biological facilities include growth room and glasshouses, SEM, autoclaves and sterile transfer area. The Laboratory is particularly well situated for studies in the Murray Darling Basin, but air links to Sydney and Melbourne also allow ready access to several major urban water storages and systems.

**THE PERSON:** The appointee must have a PhD and demonstrated research experience in a relevant discipline.

A capacity to contribute effectively to a multidisciplinary research team; and to liaise and interact with water managers is highly desirable.

**TENURE:** Appointment is for three years, with prospects for extension to five years. Commonwealth Government Superannuation is available.

**MORE INFORMATION:** Prospective applicants are invited to telephone Dr Kathleen Bowmer (069) 62 0534 for further information. Mrs Shelley McBrien (069) 62 0525 can provide a copy of the detailed job description and selection criteria.

**APPLICATIONS:** Applications should be submitted by 14 April 1989 and quote reference number GR89/2. They should be framed against the selection criteria, and should state relevant personal particulars including details of qualifications and experience. Applicants should nominate at least two professional referees and address their applications to:

**The Chief,  
CSIRO Division of Water Resources  
Private Mail Bag No. 3, Griffith, NSW 2680,  
Australia.**

*CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER* (W6007)A

## COLUMBIA UNIVERSITY Department of Anatomy and Cell Biology

Associate Research Scientist to do research on the developing enteric nervous system. Experience with molecular biology of neurotransmitter enzymes, mRNA quantitative analysis, *in situ* hybridization, and receptor neurotransmitter biochemistry required. Send curriculum vitae, statement of research goals, and names of three professional references to: **Taube P. Rothman, Department of Anatomy and Cell Biology, College of Physicians and Surgeons of Columbia University, 630 West 168th Street, New York, NY 10032. EOAAE.** (NW3526)A

POUR L'ELEVAGE  
EN AFRIQUE

## ADDIS ABABA ETHIOPIA

INTERNATIONAL LIVESTOCK CENTRE  
FOR AFRICA  
CATTLE RESEARCH NETWORK COORDINATOR  
VACANCY INT/005/89

### GENERAL

The International Livestock Centre for Africa (ILCA), with headquarters in Addis Ababa, Ethiopia is one of the 13 international agricultural research organizations which are supported by the Consultative Group on International Agricultural Research (CGIAR). The Centre has research activities throughout sub-Saharan Africa and regional offices in Kenya, Nigeria, Niger and Mali.

ILCA's major activities are research, training and information, and its goal is to achieve measurable and sustainable increases in livestock output in sub-Saharan Africa.

With purpose-built offices and research facilities on a large landscaped site close to Addis Ababa's international airport, the Centre's headquarters provide a pleasant working environment and sport and leisure facilities. The city, which enjoys pleasant weather throughout the year, has a large, diverse expatriate community and diplomatic missions from more than 75 nations. It is also the seat of the Organization of African Unity (OAU) and the United Nations Economic Commission for Africa (UNECA). There are several international schools covering American, British, French, German and Italian systems, among others.

### Position

Main duties of the Coordinator, Cattle Research Network will be:

- Plan and coordinate regional and sub-regional research on cattle.
- Guide and assist national scientists in planning and carrying out regional/sub-regional programmes.
- Assist national scientists in the analysis and interpretation of experimental data.
- Organize and run workshops and seminars.
- Solicit material for and edit the Cattle Research Network Newsletter.
- Conduct library searches and assemble a data base on cattle research.
- Prepare the annual programme of work for consideration by the Steering Committees of the Cattle Research Network.
- Prepare an annual report on the year's activities for evaluation by the Steering Committees.

### Qualifications

- A senior scientist in the discipline closely related to cattle research with a minimum of post-graduate training at PhD level and with several years experience in a developing African country. He/She should also have administrative experience.
- Should be able to work effectively with professionals of disciplines within the Cattle Research Network in a multicultural setting.
- Should be able and willing to travel extensively.
- Should be fluent in written and spoken English and/or French but with the ability to learn the other language quickly.

Salary and related benefits are paid in US\$ and will be in line with comparable international organizations. Initial salary will be determined by qualifications and experience.

Applicants should send current curriculum vitae, recent salary history, names and addresses of three professional referees and photocopies of supporting documents (not returnable) before May 30, 1989 in confidence to, the **Personnel Manager, ILCA, P.O. Box 5689, Addis Ababa, Ethiopia.** (W6016)A

## THE UNIVERSITY OF LEEDS DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY ST JAMES'S HOSPITAL NON-CLINICAL LECTURER (BIOCHEMISTRY)

Applications are invited for the above post.

Salary is on the non-clinical academic scales for Lecturers Grade A (£9260-£14500) or Grade B (£15105-£19310) (under review), according to qualifications and relevant experience.

The applications of biochemistry in the speciality are extremely broad and the applicant will have opportunities for research in almost any aspect of biochemistry. The Department has facilities for most biochemical techniques, including radio-immunoassay, HPLC and electrophoresis. Cooperation and collaboration with other Departments is encouraged and arrangements for access to their facilities and equipment can be arranged. There is significant biochemical work undertaken in other University Clinical Departments at St James's and the University has a large, well-equipped Department of Biochemistry which is very active in collaborative research. The successful applicant will be expected to undertake teaching in the Department and in the Department of Biochemistry.

Informal enquiries about the post may be made to Professor R J Lilford, Department of Obstetrics and Gynaecology, St James's Hospital, Leeds LS9 7TF (Tel (0532) 433144 Ext 5872/4524), Fax (0532) 426496).

Application forms and further particulars may be obtained from and completed applications forwarded to the **Registrar, the University, Leeds LS2 9JT** (Tel (0532) 333963 — direct line), quoting reference number 99/8. Closing date for applications 25 April 1989. (8839)A

## HORSE RACING FORENSIC LABORATORY DIRECTOR

Newmarket

circa £37,500 + car

Applications are invited for the prestigious post of Director of the internationally-renowned Horseracing Forensic Laboratory, Newmarket, which will become vacant in October 1989, on the retirement of Dr Michael Moss, MSc PhD MIBiol CChem FRSC. The Laboratory is a subsidiary of the Horserace Betting Levy Board, a statutory body which provides funds and services to horseracing.

The Laboratory, employing 55 people, provides a drug screening service to the Jockey Club, and also to provide mainly overseas, clients on a commercial basis. It also operates an extensive research programme in support of the detection of prohibited substances in racehorses.

Proven management capability is required, together with the flair, dynamism and experience in relevant scientific disciplines necessary to oversee the cost-effective, increasingly automated testing operation; to direct and motivate a team of skilled research scientists; to advise the Jockey Club on anti-doping policies and Rules and to liaise with their security and veterinary personnel; and to exploit commercial opportunities at the Laboratory as they arise. The Director will be required to keep in close touch with pharmacological developments in this country and overseas and with counterparts in other major racing countries.

The excellent benefits package includes a car and contributory pension scheme. In the first instance, please write with full CV, including current salary, to:

**Martin Crawshaw, Company Secretary, HFL Ltd,  
Horserace Betting Levy Board, 52 Grosvenor Gardens  
London SW1W 0AU. Tel: 01-730 4540 (8874)A**

## UNIVERSITY OF WALES COLLEGE OF MEDICINE INSTITUTE OF MEDICAL GENETICS (Department of Medicine)

### RESEARCH TECHNICIAN

Research Technician (Grade 4) required to work on a Muscular Dystrophy Association (USA) project, "The identification of the Myotonic Dystrophy gene". The work involves the use of recombinant DNA techniques, and candidates should have a degree in a relevant subject.

The appointment will be for one year initially with possible renewal for a further two years. Salary will be within the scale £7,505-£8,688.

Applications in the form of curriculum vitae (quoting Ref. No. M6/219) with names and addresses of two referees should be sent to the **Registrar and Secretary (Personnel Office), University of Wales College of Medicine, Heath Park, Cardiff, CF4 4XN** from whom further particulars are available (Tel. 0222/755944 Ext. 2296).

Informal enquiries can be made to Dr. D. J. Shaw (Te. No. 0222/762299).

Closing date: three weeks from the appearance of this advertisement. (8842)A

## MEDICAL RESEARCH COUNCIL

Radiobiology Unit

Chief Research Officer

A permanent position is available in the LRF Radiation Leukaemogenesis Laboratory for an experienced CELL BIOLOGIST to join a group studying the effects of ionising radiation on haemopoiesis. The person appointed will be responsible for cellular and molecular studies of changes associated with the transition from normal to eukaemic haemopoiesis in an experimental model of acute myeloblastic leukaemia. A particular objective would be to develop in-situ hybridisation techniques.

Remuneration will be at an appropriate point on MRC scales: £14,444-£16,897 (under review). An appointment would also be considered at Senior Research Officer level.

The Unit is situated on the main Harwell Laboratory site in pleasant rural surroundings equidistant to Oxford and Newbury. Excellent working conditions and research facilities, pension provision, hotel accommodation available.

Application forms and job details may be obtained from the Personnel Officer, MRC Radiobiology Unit, Chilton, Didcot, Oxon OX11 0RD. Informal enquiries are welcome to Dr. Eric Wright on 0235 834393 ext 327. Closing date: 21st April 1989.

The Council is an equal opportunity employer. (8854)A

## Research Assistant

Applications are invited for the post of Research Assistant to work on a five-year programme grant funded by the Wellcome Trust involving the structure and function of the genes encoding cell adhesion molecules in muscle and brain. Techniques involved will include mammalian cell culture, gene transfer and associated DNA/RNA analyses (see, e.g. CELL, 50, 1119, 1987; 55, 955, 1988). Experience in cell or molecular biology is preferred but training can be given. This is a responsible position in a highly active research group and should interest goal orientated individuals with interests in Molecular Biology.

Salary up to £13,330 p.a.

Applications, including a full c.v. and the names of two referees, should be sent to Dr Frank S. Walsh, Department of Neurochemistry, Institute of Neurology, The National Hospital, Queen Square, London WC1N 3BG. Tel: 01-837 3611 Ext. 4204. Closing date: 15 April 1989.

(8849)A

# KEEPER OF BOTANY

## With the vision to guide policy formulation London

The British Museum (Natural History), department of Botany, houses one of the world's largest and most important collections of botanical specimens and is held in high regard both at home and abroad for its research on the relationships, biogeography and evolution of plants.

The Keeper of Botany plays a major policy forming role within the Museum ensuring the effective financial, administrative and resource management of the department together with the leadership of a team of 49 staff including 39 scientists.

Reporting to the Museum Director you will also be responsible for the formulation, maintenance and development of the collection and for the provision of scientific and enquiry services. In addition you will represent the Museum on outside bodies and through active involvement in relevant learned societies.

An equal opportunity employer

As an active researcher with a high professional status you should have demonstrated your work through publications in relevant aspects of botany. Probably with a degree or higher qualification in Botany, you must have a knowledge of the care and maintenance of large scale collections as well as proven management and administrative abilities.

Salaries are in the range £28,170-£31,600 with further increments, depending upon performance, up to £36,785. An additional £1750 London Weighting Allowance is available.

For further details and an application form (to be returned by 28 April 1989) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 468551 (answering service operates outside office hours). Please quote ref: S/7897.

(8850)A

## HARROW HEALTH AUTHORITY THE KENNEDY GALTON CENTRE FOR CLINICAL GENETICS

Level 8 Clinical Research Centre  
Northwick Park Hospital  
Watford Road  
HARROW  
Middx HA1 3UJ

### PRINCIPAL CLINICAL MOLECULAR GENETICIST

Required to take charge of one of the two Regional DNA Laboratories which provide a diagnostic service to the North West Thames Region. The laboratory has been recently developed in new accommodation in the Centre which has a major role in the provision of genetic services to the Region.

Salary scale: £15,180-£20,989 p.a. plus £757 London Weighting. Whitley Council Conditions of Service.

Informal enquiries welcome: Telephone Dr M Ridler or Dr J Squire on 01-422-8577.

Application form and job description from the Personnel Department, Northwick Park Hospital, Watford Road, Harrow, Middlesex HA1 3UJ. Tel: 01-864-5311 ext. 2410 or 01-423-5370 (24 hours). Ref. P607X (8868)A

## DEVELOPMENTAL BIOLOGY AND NEUROSCIENCE

Two tenure track faculty positions in the Department of Anatomy Program in Cell Biology and Neuroscience. Applicants for the Associate Professor position should have an ongoing extra-murally funded research program, an established record of scholarship and a willingness to direct team-taught and problem-oriented medical gross anatomy; applicants at the Assistant Professor level should have a postdoctoral experience, an active research program, and a willingness to teach a portion of medical gross anatomy. Preferences will be given to cellular/molecular approaches to study CNS development and plasticity and to molecular studies of cell-cell interactions, proto-oncogenes, growth factors and regulation of gene expression. The Medical Center has active programs in molecular genetics, neuroscience, retinal research, aging, and ultrasonic evaluation of arterial disease. A National Biomedical Research Technology Resource Center, including IVEM, TEM, and SEM, is on campus.

Send CV and names of three references to: **Craig K. Henkel, Ph.D. Department of Anatomy, Bowman Gray School of Medicine, 300 South Hawthorne Road, Winston-Salem, NC 27103 AA/EOE.** (NW3518)A

## UNITED MEDICAL AND DENTAL SCHOOLS LEVERHULME GRANT — RESEARCH ASSISTANT

Applications are invited for a RESEARCH ASSISTANT in the Division of Anatomy, Guy's Campus. This three year post is open to applicants from October 1989, with a first or upper second class degree in human anatomy, anthropology or a related biological science. The primary aim will be to organise, preserve and catalogue a documented human skeletal collection housed in the crypts of St Bride's Church, London. The applicant will have the opportunity to work towards a PhD qualification using the skeletal collection as the basis for their research.

Salary from £8,675 per annum, plus £1,650 London Allowance.

Applications with full CV and names and addresses of two referees or any further information, to Dr J L Scheuer or Dr S M MacLaughlin, Anatomy Department, UMDS, Lambeth Palace Road, London SE1 7EH, 01 928 9292 X2490 quoting ref G/A/318 by 1 May 1989. (8844)A

The World Health Organization (WHO) is an inter-governmental agency internationally recognized for its integrity and lasting achievements. Guided by humanitarian concerns, WHO works to direct and coordinate global and national efforts to improve the health of peoples throughout the world. To meet its objectives, WHO depends on staff members with special qualities of leadership, dedication and commitment.

The Tropical Diseases Research Programme (TDR) has taken a leading role in the research and development of new and improved tools for the prevention, diagnosis and treatment of tropical diseases and now wishes to promote further development, production and testing of these new products, with specific emphasis on their production and testing in developing countries. Such new products, which include drugs, diagnostic tools, vaccines and new tools/methods for vector control, are destined for eventual integration into disease control programmes.

TDR is seeking to hire a scientist/product development manager with experience in the development, production and testing of biotechnological products and pharmaceuticals. The successful candidate will work in close collaboration with various TDR Steering Committees and will provide expertise and support related to the promotion and management of product development, particularly in relation to disease endemic countries. The product development manager will be expected to contribute to TDR's strategies for product development, including the establishment of innovative and productive interactions with industry, and to coordinate their implementation. One of the major challenges will be to initiate the development and production, in particular in developing countries, of biotechnology-derived products for use in large-scale field testing and eventual use in disease control programmes.

Applicants should have extensive experience in biotechnology or pharmaceutical research and development, ideally in a major biotechnology or pharmaceutical company, including up-to-date knowledge of the development, production and testing of biotechnological products and pharmaceuticals. A broad knowledge of the biology of tropical diseases would be an asset. A doctoral level degree in biological sciences is a requirement, as is an excellent knowledge of English or French, with a good working knowledge of the other.

Please send your detailed *curriculum vitae* and a letter of application by 30 April 1989 to **Personnel, WHO, Avenue Appia, CH-1211 Geneva 27, Switzerland, quoting PDM/TDR/89** and the name of the journal in which this announcement appeared. Applications from women are encouraged. Only candidates under serious consideration will be contacted. (W6017)A

*The UNDP/WORLD BANK/WHO special programme for Research and Training in Tropical Diseases (TDR) is a globally coordinated effort to bring the resources of modern science to bear upon the control of major tropical diseases and to strengthen the research capability of endemic, developing countries where new disease control technologies are most needed. To meet its objectives, TDR has recruited into its global network scientists of the highest calibre to participate in this international research effort.*

## TDR

### Scientist/Product Development Manager Tropical Diseases Research Programme WHO Geneva, Switzerland

## UNIVERSITY OF OTAGO Dunedin, New Zealand

### FIXED-TERM LECTURESHIP (SCIENCE) IN BIOCHEMISTRY

Applications are invited from science graduates with appropriate experience for appointment to a fixed-term Lectureship in Biochemistry. The appointment is for a period of 12 months, which is to fill a vacancy created by the absence of a permanent member on leave without pay, not subject to extension or renewal. The post will be available for three years from approximately 1 July 1989.

Salary: NZ\$35,000-NZ\$42,000 per annum.

The appointment, which will be made at a level that is suitable for a recent Ph.D. graduate, is open to applicants with research experience in any branch of Biochemistry, Molecular Biology and would provide experience in a University Department for a graduate who wishes to make a career in academic biochemistry. Extensive postdoctoral experience is not an essential pre-requisite.

Further particulars are available from Appointments (36182) Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF; or from the Registrar, University of Otago, P.O. Box 56, Dunedin, New Zealand. Enquiries may be addressed to the Head of the Department of Biochemistry, Professor G.B. Petersen, Fax: NZ (024) 741 607 or by telephoning: NZ (024) 797 864.

Applications quoting reference number A89/15 close on 1 July 1989.

Equality in Employment opportunity is University Policy. (W6014).

## UNIVERSITY OF LIVERPOOL

### Department of Biochemistry

#### Protease and Proteolysis Research Group

Applications are invited for the post of postdoctoral

### Senior Research Assistant

Funded by the S.E.R.C. Biotechnology Directorate to study the action of metallo-endopeptidases in the synthesis of biologically-important peptides and peptide derivatives. The project will be conducted in collaboration with Dr. R. Cosstick, Department of Chemistry. Informal enquiries may be made to Dr. R. J. Beynon, Tel. 051-794 4359.

The post is tenable immediately for a period of up to three years at an initial salary within the range £9,865 - £11,680 per annum. Applications, together with the names of three referees, should be received as soon as possible by **The Director of Staffing Services (AS), The University, P.O. Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained.**

Quote ref. RV/308/N.

An Equal Opportunity Employer (8840)A

## UNIVERSITY OF DURHAM

### DEPARTMENT OF GEOLOGICAL SCIENCES

### RESEARCH POST IN SEISMOLOGY

Applicants are invited for the post of Research Assistant or Senior Research Assistant in Earthquake Seismology to be responsible for running a seismic network in the Caribbean. Candidates should preferably have practical experience in seismic acquisition, and research experience in seismology. Consideration will also be given to applicants with a practical electronics background. Informal enquiries concerning the appointment may be made to Dr. R. E. Long (Tel. 091-374-2512).

The post will be of one year's duration starting in Autumn 1989. The appointment will be on Research and Analogous IB (£8,675-£11,680) or IA (£9,865-£15,720) according to qualifications and experience.

Further particulars may be obtained from the **Registrar, Science Laboratories, South Road, Durham, DH1 3LE (Tel. no. 091-374-2264)** to whom applications (three copies), including the names of three referees, should be sent not later than Monday, 17th April, 1989. (8881)A

## UNIVERSITY COLLEGE LONDON

### Department of Biochemistry

### Novel Restriction Enzymes

Technician required for a joint research project with New England Biolabs Inc. to isolate novel restriction enzymes from our extensive culture collection. The position will involve some travel to New England Biolabs laboratories in the USA plus other benefits and can start immediately. Salary £8386 inclusive. Experience of protein purification and/or microbiological techniques would be preferred.

Please telephone or send c.v. plus names of two referees to **Dr. J M Ward, Dept. of Biochemistry, University College London, Gower Street, London WC1E 6BT.** Telephone. 01-387 7050 ext. 2242. Equal Opportunities Employer. (8859)A

## FACULTY POSITIONS MOLECULAR ONCOLOGY AND DEVELOPMENT

Exciting opportunities at levels exist in new programs at Yale University, to be filled over the next 2-3 years. Individuals with research interests in the molecular aspects of oncology or the development of molecular organisms are invited to apply. Qualified candidates, Ph.D. or MD, will have completed at least 2 years of productive postdoctoral research and will be expected to establish independent programs.

Interested applicants should submit a CV, along with a summary of research interests, a list of 3 letters of reference to be sent to: **Dr. Sherman M. Weinman, Search Committee, Yale University School of Medicine, P.O. Box 3333, New Haven, CT 06510.**

## BIOCHEMICAL GENETICIST

The Department of Pediatrics, University of Arizona College of Medicine, is seeking a geneticist with primary research emphasis in basic biochemical or molecular genetics to join an active section with one molecular and two clinical geneticists. Qualifications should include the M.D. and/or Ph.D. degree and ABMG board certification or eligibility in clinical biochemical genetics. The position is at the assistant professor level in the tenure track and will be an integral part of a new Mammalian Molecular and Developmental Genetics Unit in The Children's Research Center. Contact: **H. Eugene Hoyme, M.D., Chief, Section of Genetics/Dysmorphology, Department of Pediatrics, University of Arizona College of Medicine, Tucson, AZ 85724. Telephone: (602) 795-5675.** The University of Arizona is an EEO/Affirmative Action Employer. Closing date is 5/15/89 or when position is filled. (NW3528)A

## POSTDOCTORAL POSITION

Available now to investigate mechanisms of regulation of lipoprotein lipase and hepatic lipase gene expression, protein synthesis, and catalytic activities. Cell culture (liver, adipocyte, endothelial), molecular biology, immunochemical (monoclonal antibodies), and recombinant DNA technique approaches are employed. Applicants should have training in biochemistry or molecular biology. Experience with recombinant DNA desirable. Send résumé and names of three references to: **Dr. Andre Bensadoun, Division of Biological Sciences and Nutritional Biochemistry, 321 Savage Hall, Cornell University, Ithaca, NY 14853.** (NW3523)A

## UNIVERSITY OF AUCKLAND New Zealand

DEPARTMENT OF CELLULAR AND  
MOLECULAR BIOLOGY

## POSTDOCTORAL POSITION

To study the effects of cyclic AMP on growth and differentiation of tumour cells, particularly effects on phosphatidylinositol metabolism and possible involvement of oncogenes. Experience in these areas would be advantageous. The position is available for 2 years and includes a return airfare. For further information contact Professor Ray Ralph, Department of Cellular and Molecular Biology, University of Auckland, Private Bag, Auckland, New Zealand. Tel: 64 9 737 999, Fax: 64 9 31 618. (W6004)A

## Staff Scientists/Biochemistry/ Molecular Biology/ Fermentation Technology

CIBA-GEIGY has immediate openings for staff/senior scientists in the Biotechnology Department of its Pharma Research Division. The positions will involve the expression of recombinant proteins in microorganisms, mainly yeast, with emphasis on host strain improvement by physiological/fermentation means.

The qualified individuals will have a PhD in microbiology/biochemistry with a strong background in molecular biology or, alternatively, in biochemical engineering, 2-4 years postdoctoral and/or industrial experience, written and oral communication skills as well as a commitment to team work.

We provide a stimulating professional atmosphere with many opportunities for collaborative projects with small Biotech companies as well as University Institutes. We offer competitive salaries and a comprehensive benefit program. For consideration please forward your CV, list of publications and the name of three referees under ref. "Nature 347" to **Mr. H. Schmid, CIBA-GEIGY Ltd., Personnel Department, P.O. Box, CH-4002 Basle.** (W6008)A

# CIBA-GEIGY

## UNIVERSITY OF READING Lectureships in Microbiology

Applications are invited for two Lectureships in the Department of Microbiology, School of Animal and Microbial Sciences. The preferred areas are Molecular Virology, Bacteriology or Molecular Immunology of Infectious Diseases but applications from candidates with interests in other areas of microbiology will be considered. The appointees will be expected to initiate independent research programmes through obtaining external funding and to contribute to the teaching and administrative commitments of the Department and the School. The Microbiology Department, will shortly move into new purpose built laboratories which will have generous space and excellent facilities and research. Salary scale £9,260 to £14,500 p.a. (Grade A) — under review — plus USS benefits. For particulars and application forms (2 copies) are available from Personnel Office, University of Reading, Whiteknights, PO Box 217, Reading, RG6 2AH, telephone 0734-318751. Candidates from overseas need only send a CV and the names of two academic referees. More information about these attractive posts may be obtained from **Professor J.W. Almond, Department of Microbiology, tel: 0734-318901.** Please quote Ref. AC. 8915. Closing date 24 April. (8838)A

## ST. MARY'S HOSPITAL MEDICAL SCHOOL

(a constituent College of Imperial College of Science, technology and Medicine)  
(University of London)  
Norfolk Place, London W2 1PG

## WOLFSON POST-DOCTORAL RESEARCH FELLOW

required to join group in the Academic Department of Medicine at St. Mary's Hospital Medical School (Head of Department: Professor H.C. Thomas) to work on the molecular biology of delta hepatitis virus. Previous experience in gene cloning and general molecular biology techniques will be an advantage. Post funded by the Wolfson Foundation for a period of three years with starting salary of £13,330 pa inclusive of London Allowance. Further enquiries to Dr. J. Monjardino (01-725-6381/1606).

Applications in form of a full C.V. with names and addresses of 2 referees should be sent to Personnel Department at above address. Please quote: Ref. 591. (8876)A

# UNIVERSITY of GUELPH

## DEPARTMENT OF VETERINARY MICROBIOLOGY AND IMMUNOLOGY

### Applications are invited for a tenure track position as **ASSISTANT PROFESSOR**

in veterinary immunology. Responsibilities include supervision of the Clinical Immunology Laboratory of the Veterinary Teaching Hospital, research, and teaching. Research opportunities exist in the fields of immunological diseases and diagnostics with the possibility of collaboration and consultation in production and application of conventional and genetically engineered monoclonal antibodies.

Applicants should have a Ph.D. and preferably a DVM degree with experience in laboratory diagnostics and in monoclonal antibody production. A central interest in diagnostic immunology including both applications and development, is essential.

In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents.

Please address enquiries to **Dr. Bruce Wilkie, Chairperson, Department of Veterinary Microbiology and Immunology, Ontario Veterinary College, University of Guelph, Guelph, Ontario, Canada, N1G 2W1.** Applications will be accepted until May 31, 1989 or until the position is filled. Subject to final budgetary approval.

*The University of Guelph is committed to Employment Equity.*  
(NW3519)A

## UNIVERSITY OF NEWCASTLE UPON TYNE THE MEDICAL SCHOOL

### **BAYER LECTURESHIP IN PHARMACOGENETICS**

Applications are invited for the post of Lecturer in Pharmacogenetics, tenable with immediate effect and for an initial period of five years. The postholder will work with Professor J R Idle in the Basic Pharmacology Section of the Department of Pharmacological Sciences and will be expected to play a leading role in the local development of human pharmacogenetics. Candidates should be non-medically qualified, hold a higher degree and have established themselves in the fields of pharmacology, toxicology, drug metabolism or human genetics. Research facilities comprise newly refurbished laboratories provided with gas chromatography, molecular biology and cell culture equipment. The Department is involved in both undergraduate and postgraduate teaching and the successful candidate would be expected to contribute to a broad range of teaching activities.

Salary will be at an appropriate point on the Lecturers' scale A £9,260-£14,500 p.a. or exceptionally on the Lecturers' scale B £15,105-£19,310 p.a. according to experience and qualifications.

Potential applicants are welcome to discuss the post with Professor J R Idle (091-222-7675). Further particulars may be obtained from the **Senior Assistant Registrar, Establishments, The University, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU** with whom applications (three copies) together with the names and addresses of three referees should be lodged not later than 5th May 1989.

(8877)A

## **RESEARCH ASSISTANT**

Applications are invited for a Research Assistant to work on a project utilising molecular techniques to investigate the mechanisms underlying numerical and structural abnormalities of chromosome 18 in man. The post is funded for a period of three years by Action Research for the Crippled Child and is suitable for

1) a Post Graduate with a first or second class honours degree. (It may be possible for such an applicant to register for a higher degree) or

2) an Individual with a Higher Degree.

Experience in Molecular Genetics is Essential. Salary £8,548-£11,073. Enquiries to **Dr Patricia A. Jacobs or Dr John Harvey at the WESSEX REGIONAL CYTOGENETICS UNIT. Telephone 0722 336212 extension 669.** Application forms from the **Personnel Department, Odstock Hospital, Salisbury, Wilts SP2 8BJ.**

Closing date: 20th April, 1989

(8867)A

## INTERNATIONAL CENTRE FOR MEDICAL RESEARCH (CIRMF) FRANCEVILLE, GABON

### **Reproductive Physiologist/ Primatologist**

A post-doctoral scientist is required to assist in developing a research programme on the hormonal regulation of reproductive behaviour and fertility in non-human primates. The position is available on a two year contract (renewable) commencing Autumn 1989. An attractive salary is offered plus relocation, expatriation and education allowances, housing on the CIRMF campus and 60 days paid annual leave.

Applicants should submit a curriculum vitae and names and addresses of 3 referees to: **Dr G. E. Roelants, Deputy Director General, Scientific Director, CIRMF, BP 769, Franceville, Gabon.** Closing date: 31st May 1989.  
(W6005)A

## THE AFRC INSTITUTE OF HORTICULTURAL RESEARCH

Littlehampton, West Sussex  
Scientific Officer

A Scientific Officer is required in the Entomology and Insect Pathology Section to work on the control of mushroom flies using rhabditid nematodes (*Steinernema*, *Heterorhabditis* spp.) The major aim of this work is to develop biological control strategies both for scarid flies and for the larvae of *cecidiomyiid* pests.

Qualifications: First or Upper Second Class honours degree in appropriate subject or equivalent.

Salary: In range £8,574 - £10,994

Further details and application form quoting Ref 29/L from The Personnel Officer, Bradbourne House, East Malling, Maidstone, Kent ME19 6BJ. Closing date 20th April 1989.

The AFRC is an Equal Opportunities Employer. (8869)A

## **POSTDOCTORAL POSITION NEUROPHYSIOLOGY**

Applications are invited for a post-doctoral position concerning projects with ion-selective micro-electrode techniques on cultured astrocytes and neurons. Applicants should have a background in neurophysiology and experience with electrophysiological recording. Salary will be on MRC (Canada) scales. Applications including CV and names of three referees should be sent to:

**Dr. Wolfgang Walz, Department of Physiology, College of Medicine, University of Saskatchewan, Saskatoon, Sask. S7N 0W0, Canada.**  
(NW3520)A

## UNIVERSITY OF ALBERTA FACULTY OF DENTISTRY

### **ORAL MICROBIOLOGY**

Applications are invited for a tenure-track position in the Division of Pathology in the Department of Oral Biology available from July 1989. Applicants must have a dental degree, and graduate training and at least 2 years postdoctoral research experience in oral microbiology and be prepared to teach in oral microbiology and, to more limited extent, in oral pathology. Preference will be given to applicants with a higher degree (PhD or equivalent) and additional teaching experience in anatomy, biochemistry, physiology, pharmacology or clinical discipline. Rank and salary are commensurate with education and experience of an Assistant Professor (\$32,564-46,700) or Associate Professor (\$40,810-58,954). The University of Alberta is committed to the principle of equity in employment. In accordance with Canadian Immigration requirements, priority will be given to Canadian citizens and permanent residents. Applications including curriculum vitae and the name of 3 referees should be sent, no later than April 30, 1989 to:

**Dr D.M. Paton, Professor and Chairman, Department of Oral Biology, University of Alberta, Edmonton, Alberta, Canada T6G 2N8.**

## UNIVERSITY OF HONG KONG

### Lecturer in Biochemistry

Applications are invited for a Lectureship in the Department of Biochemistry. The appointee will participate in the teaching of students in the Faculties of Medicine, Science and Dentistry. Present research activities in the Department include molecular biology, membrane, developmental and neurobiochemistry, enzymology, immunology and haematology. Consideration will be given to applicants from ANY field of research. Those who are interested in contributing to the teaching of human genetics of lipid biochemistry are encouraged to apply. A higher degree is normally expected and some teaching experience is desirable. Applicants with medical or dental qualifications may have an advantage.

Annual salary (superannuable) is on an 11-point scale: HK\$206,040-44,400 (approx. 15,260-25,510 sterling equivalent as at March 3, 1989). Starting salary will depend on qualifications and experience. A medically qualified appointee who has just completed his pre-registration year will be appointed as Lecturer at the minimum point of the scale. At current rates, salaries tax will not exceed 15.5% of gross income. Children's education allowances, leave, and medical benefits are provided; housing or tenancy allowances are also provided in most cases at a charge of 7.5% of salary.

Further particulars and application forms may be obtained from Appointments (36160), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF, U.K., or from the Appointments Unit, Registry, University of Hong Kong, Hong Kong. Closing Date: 9 June 1989. (W6011)A

## UNIVERSITY OF OTAGO Dunedin, New Zealand LECTURER IN BIOORGANIC CHEMISTRY

### Department of Chemistry

Applications are invited from women and men for a Lectureship in the Department of Chemistry. The appointment, part of a programme to attract younger members of staff, is seen to be important in developing a significant chemical presence in biological science in this University.

The main criterion is distinction in research but the successful candidate will be expected to contribute to the undergraduate teaching programme in the Department. Candidates are expected to have a sound background in organic chemistry which will enable them to teach at all levels but the research experience in biological organic chemistry will be interpreted in the broadest sense.

The appointment will be for three years in the first instance and salary will be within the lecturers scale NZ\$35,000-NZ\$42,500 per annum depending on qualifications and experience.

Enquiries may be made to Professor B.H. Robinson, Department of Chemistry, FAX NZ(024) 741-607, by telephoning NZ(024) 797-907 or E-Mail CHEMMAIL@Otago.AC.NZ.

Further particulars concerning the post are available from the Registrar, Mr D.W. Girvan, P.O. Box 56, Dunedin, New Zealand or from Appointments (36168), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF, U.K.

Applications quoting reference A89/11 close 22 May 1989.

Equal opportunity in employment is University policy (W6015)A

## DEPARTMENT OF BIOCHEMISTRY UNIVERSITY OF OXFORD

### MRC IMMUNOCHEMISTRY UNIT GRADE 4 TECHNICIAN (FULL-TIME or PART-TIME)

BT/291

Candidates are invited to apply for a Research Technician post in this Unit to work on proteins of the immune system. Duties will include assisting with experiments involving recombinant DNA techniques, protein and peptide characterisation, the maintenance of mammalian cell lines as well as the general organisation of the laboratory.

Applicants are expected to have at least ONC/OTEC qualification and have a minimum of three year's relevant experience in a biochemical laboratory.

Salary on the scale £7,505-£8,685 depending upon age and experience. The appointment is for 5 years in the first instance with the possibility of renewal.

Applications including a curriculum vitae and the names and addresses of two referees should be sent to: **The Administrator.**

An Equal Opportunity Employer.

(8878)A

DEPT OF BIOCHEMISTRY, SOUTH PARKS ROAD, OXFORD, OX1 3QU.

## UNIVERSITY OF MASSACHUSETTS — AMHERST DEPARTMENT OF CHEMICAL ENGINEERING

invites applications for

### FACULTY POSITIONS

available at all levels. Area of specialization is open, but we are particularly interested in individuals with a strong background in nonlinear dynamics and computation, willing to interact with a wide spectrum of research groups within the department. For Full Professor the department seeks an individual who is an outstanding educator and scholar, and who can provide innovative and dynamic leadership in chemical engineering research and education. Qualifications for the Assistant or Associate Professorship include a Ph.D. in Chemical Engineering, a commitment to graduate and undergraduate teaching, and potential for developing a strong externally sponsored research program. Salary commensurate with qualifications and experience. Applications are accepted up to May 20, 1989.

Please send a resume, brief statement of teaching and research interests, and names of three references to: **Chairman, Search Committee, Department of Chemical Engineering, University of Massachusetts, Amherst, MA 01003.**

The University of Massachusetts is an Affirmative Action/Equal Opportunity Employer. (NW3512)A

## PUBLIC HEALTH LABORATORY SERVICE BOARD

### PHLS CENTRE FOR APPLIED MICROBIOLOGY & RESEARCH

### DIVISION OF PATHOLOGY DIAGNOSTICS GROUP

### BASIC/SENIOR GRADE MICROBIOLOGISTS

Graduate or postgraduate microbiologists are required to join the Diagnostics Group.

The work will involve the development of laboratory diagnosis of Arboviral and Bacterial (including Rickettsial) diseases. Candidates should be familiar with current developments in the detection of antigens and antibody applied to the diagnosis of acute

infectious disease.

The period is initially for 3 years and has vacancies for 2 Basic Grade and 2 Senior Grade Microbiologists.

Further information may be obtained from Dr G. Lloyd or Dr D. Rutter, tel: (0980) 610391.

Salary scale: BGM £7378-£11073  
SGM £11778-£15394

NHS terms and conditions will apply.

Application forms can be obtained from the Personnel Officer, PHLS Centre for Applied Microbiology & Research, Porton Down, Salisbury, Wilts SP4 0JG. Tel: (0980) 610391, to whom completed forms should be returned by 14th April 1989 quoting Post No. 0322/0325. (8863)A

## UNIVERSITY OF CAMBRIDGE DEPARTMENT OF MEDICINE

### Research Technician

Applications are invited for a research technician post in a University funded appointment to study autoimmune responses in human renal disease. The work will involve cell culture, radioimmunoassay and high performance liquid chromatography techniques. Salary in range £7,700-£10,000 per annum depending on qualifications and experience.

### Post doctoral Research Officer

Applications are invited from appropriately qualified scientists to study humoral aspects of autoimmune renal disease in man. Applicants should have experience in molecular biology or immunology. Appointment is Wellcome funded and for two years in the first instance. Starting salary up to £12,000 per annum according to age and experience.

Further details can be obtained from **Dr C.M. Lockwood, School of Clinical Medicine, Addenbrooke's Hospital, Hills Road, Cambridge CB2 2QQ (Tel. 0223 336744)** to whom applications should be sent, together with a CV and the names and addresses of two referees. (8875)A

## LEICESTER UNIVERSITY DEPARTMENT OF PHYSICS

### X-ray Astronomy Group

#### DEPUTY MANAGER FOR THE ROSAT WIDE FIELD CAMERA QUICK-LOOK FACILITY

The Wide Field Camera (WFC) is an XUV telescope built by a consortium of five U.K. research groups which will form part of the German/U.K./U.S. X-ray astronomy satellite ROSAT, due for launch in February 1990. In order to monitor the functioning of the WFC and the quality of scientific data returned, a "Quick-Look Facility" (QLF) will be established at the Max Planck Institut fuer Extraterrestrische Physik near Munich. A deputy to the QLF Manager is required to oversee the day-to-day operation of the computer and the execution of procedures to process and analyse data received from the satellite. After an initial period of training in the U.K. the successful candidate will be transferred to Munich about 6 months prior to the launch of ROSAT.

Candidates should have a Ph.D. or equivalent experience, in Physics, Astronomy or a related field, and must have experience in software development and the operation of computers running DEC-VAX/VMS. Experience of data analysis in the field of satellite astronomy and an interest in X-ray astronomy would be advantageous. The post is available immediately and the contract will be for a period of 12 months, though it is expected that funding for the post will be continued for the duration of the ROSAT mission of at least 2 years. Starting salary will be in the range £9,865 to £12,760, on a scale up to £15,720, depending on qualifications and experience. Foreign service allowances will be paid for relocation to Munich.

Applications, which should include a C.V. and names and addresses of two referees, should be sent to **Dr. J.P. Pye, Department of Physics, The University, Leicester LE1 7RH**, by 20th April 1989. Further details are also available from Dr. Pye. (8865)A

**GBF Gesellschaft für Biotechnologische Forschung mbH, Braunschweig, FR Germany** — a government supported Research Institute of Biotechnology — offers two

### Postdoctoral Positions

for two years available immediately to support running research programs in the Department of Genetics on "factors affecting bone cells":

1. Purification, characterization and cloning of a peptide hormone receptor. Experience on assaying receptor-ligand-interaction, on protein purification will be required; familiarity with recombinant DNA-technology is desirable (ref. no. 37/89).
2. Histological analyses with immunotechniques and in-situ hybridisation of bone and various cells that metabolize bone, measurement of bone growth in conjunction with selected growth factors (ref. no. 38/89).

Applications should be addressed to the **Personnel Dept., GBF, Mascheroder Weg 1, D-3300 Braunschweig, FRG**. Please include a complete c.v., list of publications, details of research activities to date and the names and addresses of two referees. Informal enquiries can be made to Dr. H. Mayer (Tel. 531/6181-213). (W6010)A

## UNITED MEDICAL AND DENTAL SCHOOLS OF GUY'S AND ST THOMAS'S HOSPITALS

### Division of Biochemistry

Applications are invited for a

### Lectureship in Biochemistry

The successful applicant will be based on the St Thomas's Hospital site and should be prepared to teach also on the Guy's Hospital site.

One of the major interests in the Division of Biochemistry is the Neurosciences but this should not discourage applicants with other backgrounds. Intending applicants should have some post-doctoral experience in Biochemistry or related subjects.

The salary will be on the non-clinical lecturer scale (Grade A) £9,260-£14,500 plus London Weighting Allowance of £1,650, though consideration may be given to exceptional candidates above this range. The appointment is expected to begin on 1 October 1989. Further information can be obtained from Professor H S Bachelard, Division of Biochemistry on 01-928 3619.

Applications with full Curriculum Vitae (six copies), and the names and addresses of two referees should be sent to the **Personnel Officer, UMDS, St Thomas's Campus, Lambeth Palace Road, London SE1 7EH** quoting reference STH/BIO/319 by 1 June 1989. (8858)A

## UNIVERSITY OF ZIMBABWE

Applications are invited for the following posts:

ASSOCIATE  
PROFESSORSHIPS/  
SENIOR LECTURESHIPS/  
LECTURESHIPS

DEPARTMENT OF  
BIOLOGICAL SCIENCES

### POST A RANGELAND ECOLOGIST

The Ecologist should have experience in tropical or subtropical rangelands and will be expected to contribute to the MSc Programme in Tropical Resource Ecology. The successful candidate should possess a PhD in the appropriate discipline or equivalent research experience.

### POST B BIOMATHEMATICIAN

A Biomathematician is required: (1) to advise and assist academic staff and postgraduate students in the Department of Biological Sciences with the design analysis and interpretation of research projects as well as the mathematical modelling of Biological phenomena and, (2) to teach courses on basic statistical procedures and computer usage to Biology students at postgraduate and undergraduate levels. Experience in the mathematical analysis and modelling of natural phenomena at all levels including physiology, population and the ecological aspects will be an advantage. A PhD or equivalent experience would be the normal qualifications.

### POST C ENTOMOLOGIST

An experienced Entomologist is required. The lecturer should be capable of contributing to the planning and running of an MSc Programme incorporating Taxonomy, pesticides and other applications, Biological control, Physiology and Biology of crop pests and will also need to teach undergraduate courses in Entomology. A PhD or equivalent research experience would be the normal minimum qualification.

### POST D BOTANIST

A Botanist with wide interests and training is sought. The successful candidate will lecture to first year students in the Plant Kingdom Course and will be expected to

contribute to second and third year teaching and to postgraduate supervision. A PhD or go Honours degree plus equivalent research experience would be the normal minimum qualification.

### POST E ANIMAL ECOLOGIST

The successful applicant will be responsible for undergraduate courses, in addition to teaching and supervisory contributions, an MSc Programme in Tropical Ecology. Ideally, candidates should have a proven record in the supervision of postgraduate students preferably in large mammal ecology, although other areas may be considered. A PhD or equivalent research experience would be the normal minimum qualification.

### DEPARTMENT OF CHEMISTRY (PHYSICAL CHEMISTRY)

Candidates should have a relevant PhD degree and lecturing research experience. Preference may be given to candidates oriented towards reaction kinetics and thermodynamics and their applications.

**SALARY SCALE:** Non-Medical Lecturer: Z\$19,860-Z\$28,170; Senior Lecturer: Z\$29,170-Z\$31,572; Associate Professor: Z\$32,532-Z\$33,624. Appointment on the above scales will be according to qualification and experience.

### CONDITIONS OF SERVICE

Both permanent and short-term contracts are offered. Persons who are not Zimbabwean citizens may be appointed only on a short-term contract basis for an initial period of two years. Short-term contracts may be extended.

Applications should quote a reference number of the advertisement (ASA/7/02/89) and submit six copies of applications giving full personal particulars which should include full name, place and date of birth, qualification, employment and experience, present salary, date of availability, telephone number and names and addresses of three referees, to the Deputy Registrar (Administration) University of Zimbabwe, PO Box MP167, Mount Pleasant, Harare, Zimbabwe (Telex: 4-152 ZW).

Applicants from outside Zimbabwe should also send a copy to Appointments, Association of Commonwealth Universities, Gordon Square, London WC0E 0PF, U.K.

Closing date for the receipt of applications is 14 April 1989.

of science

## RESEARCH ENGINEERS Caltech Submillimeterwave Observatory

The California Institute of Technology in Pasadena, CA operates a submillimeterwave observatory at the Mauna Kea site in Hawaii. Receivers, spectrometers, and electronic and computer support systems are being constructed to allow operation in both radiometric and spectroscopic modes, throughout the frequency range 200-1,000 GHz. Positions are available for engineers, physicists or astronomers with experience in any of the following areas: radio electronics, radio astronomy techniques, millimeter or submillimeter receivers, liquid helium temperature cryogenics, bolometers and superconducting tunnel junction techniques. Senior and junior positions are available at Caltech in Pasadena. Some additional job opportunities associated with the Caltech observatory are available in Hawaii.

Applicants should have at least a B.S. degree in engineering, physics or astronomy.

Applications should be sent to Manager of Employment, California Institute of Technology 101-6, Pasadena, CA 91125, and should include a summary of education and relevant job experience.

Caltech is an Affirmative Action/Equal Opportunity employer. Women and minorities are encouraged to apply (NW3527)A

## DEPARTMENT OF BIOCHEMISTRY UNIVERSITY OF OXFORD

### GENETICS LABORATORY POSTDOCTORAL RESEARCH ASSISTANT — Grade 1A BR/290

A Postdoctoral Research Assistant is required to join a team comparing the applications of pulsed field electrophoresis and the polymerase chain reaction with standard methods of carrier diagnosis in Duchenne Muscular Dystrophy.

Position available for one year with potential for renewal. Based at the Churchill Hospital, in close collaboration with the Genetics Laboratory in the Department of Biochemistry.

Salary on the scale £9,865-£15,720 per annum.

Applications, including the names and addresses of two referees, should be sent, as soon as possible to: **The Administrator.**

*An Equal Opportunity Employer.*

(8879)A

DEPT OF BIOCHEMISTRY, SOUTH PARKS ROAD, OXFORD, OX1 3QU.

### THE UNIVERSITY OF MANCHESTER RESEARCH ASSISTANT/ASSOCIATE IN THE DEPARTMENT OF MEDICINE

Applications are invited for this post in the University Hospital of South Manchester, to examine cellular interactions in human melanoma. The appointee will have experience of cell culture and protein chemistry techniques. This is a two year appointment supported by the R.L. Gardner Bequest Fund at Withington Hospital. Salary in range £8,675-£12,150 p.a. according to qualifications and experience. Applications, with the names of two referees should be submitted to

**Dr. D. Woolley, University Hospital of South Manchester, West Didsbury, Manchester M20 8LR,** as soon as possible.

*The University is an equal opportunities employer.* (8851)A

Delta Biotechnology Limited, a subsidiary of Bass Plc, specialises in the manufacture of human healthcare products. The Company is located in central Nottingham where it is now building a large pilot plant, designed for the production of rDNA products in compliance with Good Manufacturing Practice.

We are now commencing a phased recruitment schedule for this plant, the first phase of which is to attract the key people to form the plant managerial team and to become involved from the start of equipment installation through to successful operation.

These positions will require people with an excellent track record within the pharmaceutical/biotechnology industry and a high level of commitment to the successful operation of this plant.

## Senior Fermentation Supervisor

This position requires a good academic background (Life Sciences/Biochemical Engineering) in addition to at least 5 years industrial experience within the area of fermentation and cell separation at pilot plant/production scale. The ability to communicate with all levels of staff is essential and the candidate must be able to demonstrate good supervisory skills. Experience of working in compliance with GMP guidelines is highly desirable.

## Senior Downstream Processing Supervisor

This position requires a good academic background (Life Sciences/Biochemical Engineering) in addition to at least 5 years industrial experience within the area of downstream processing at pilot plant/production scale. Experience of working in compliance with GMP guidelines and the ability to communicate with all levels of staff is essential. The candidate must be able to demonstrate good supervisory skills and experience of clean room/sterile room operations would be an advantage.

Attractive remuneration packages commensurate with age and experience will be offered with regard to the above positions.

Please write with full c.v. to:-

**Peter Lees, Delta Biotechnology Ltd.,  
Castle Court, 59 Castle Boulevard,  
Nottingham NG7 1FD.**

## ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND

### Anatomical Society Research Studentships

Applications are invited from Departments of Anatomical Sciences in the UK and Ireland for Research Studentships tenable in the Anatomical Sciences for a period up to three years. Students nominated by Departments must be graduates of British or Irish Universities and will be expected to register for a higher degree. The stipend will be commensurate with basic Research Council rates.

### Anatomical Society Senior Visiting Fellowship

Applications are invited from Overseas Scientists for one Fellowship tenable for a period of less than a year in a Department of Anatomical Sciences in the UK or Ireland. Applicants should be of post-doctoral or comparable status and must have arranged sponsorship in the Department in which they intend to work. Some assistance towards travel and subsistence will be provided.

Further particulars should be obtained from the Acting Secretary, Dr Ian Whitmore, Department of Cell and Structural Biology, Stopford Building, University of Manchester, Oxford Road, Manchester M13 9PT, to whom applications should be sent by 28 April 1989.

(8606)A

## PUBLIC HEALTH LABORATORY SERVICE BOARD PHLS CENTRE FOR APPLIED MICROBIOLOGY & RESEARCH DIVISION OF BIOLOGICS PROTEIN CHEMISTRY SECTION

Biochemist/Immunologist (Senior Grade Microbiologist) — Post No. 0550

A biochemist is required to join a research group involved in the study of bacterial protein toxins. The successful applicant will be responsible for developing immunoassays for several protein toxins with an emphasis on producing novel, rapid assay methods. Applicants must have drive, be able to work independently and should have at least four years postgraduate experience preferably with a PhD in a relevant field. Experience in hydridoma technology and immunoassay techniques would be an advantage although not essential.

Salary will be in the range £11,778-£15,394, depending on experience.

The position will be funded initially for a period of three years.

NHS terms and conditions will apply.

Application forms can be obtained from the Personnel Officer, PHLS Centre for Applied Microbiology & Research, Porton Down, Salisbury, Wilts SP4 0JG. Tel: (0980) 610391, to whom completed forms should be returned by 14th April 1989 quoting Post No. 0550 (8862)A

## Imperial College of Science, Technology and Medicine. (University of London) BIOCHEMISTRY DEPARTMENT RESEARCH ASSISTANT

A graduate research assistant is required to join a small group engaged in producing a physical map of the short arm of human chromosome 11. The project involves cosmid cloning, DNA fingerprinting and data analysis by computer. Some experience in DNA manipulation is desirable, but not essential.

Salary on RAIB scale from £8675-£11680 depending on age and experience plus London Allowance £1650. This position is available immediately.

Applications with CV and names of 2 referees and informal enquiries to Dr. P.F.R. Little, Biochemistry Dept., Imperial College of Science, Technology and Medicine, Imperial College Road, London, SW7 2AZ. Tel: 01-589-511 EXT. 4164. Ref: BIO/AD/24 (8866)A

## IMMUNOLOGIST / VIROLOGIST

Laboratory of Infectious Diseases  
National Institute of Allergy and Infectious Diseases  
National Institutes of Health

Position available immediately for qualified immunologist or virologist to work in the Respiratory Viruses Section, NIAID, NIH. Work will involve a detailed characterization of the cellular immune response to respiratory syncytial viruses (RSV) proteins and an investigation of the immunological mechanisms underlying the enhanced disease seen in recipients of inactivated virus vaccine following natural infection with RSV. A Ph.D. in immunology, virology or molecular biology is required.

Salary range: \$24,000 - \$27,000

Qualified and interested candidates should send curriculum vitae, Application for Federal Employment (SF-171) and names and addresses of three (3) references to:

Brian R. Murphy, M.D.  
Head, Respiratory Viruses Section  
NIAID, NIH  
Bldg. 7, Room 106

## POSTDOCTORAL POSITIONS

### EUKARYOTIC MOLECULAR GENETICS

Available immediately for study of the genetics of the opportunistic AIDS pathogen, *Pneumocystis carinii*. Experience in molecular genetics, biochemistry or molecular pathogenesis required. Send c.v. and three letters of reference to: Dr. G. A. Buck, Box 678 MCV Station, Va Commonwealth Univ., Richmond, Va. 23298.

## POSTDOCTORAL RESEARCH ASSOCIATE

to develop nonconventional systems for crop improvement. Two-year appointment at \$22,000 per year, available immediately. Funded by the Christine Lee Shepard Memorial Fund, established to promote innovative research for plant improvement. Required: Ph.D.; training in recombinant DNA and/or plant tissue culture. Send curriculum vitae, including coursework transcripts, a statement of research interests, and have three letters of reference sent by 15 April 1989 to: Dr. Frank White, Department of Plant Pathology, Throckmorton Hall, Kansas State University, Manhattan, KS 66506. Telephone: 913-532-6176. *Equal Opportunity/Affirmative Action Employer.*

## MOLECULAR IMMUNOLOGIST BRANDEIS UNIVERSITY

The Rosenstiel Research Center and the Department of Biology, seek a tenure-track Assistant Professor in the area of the molecular biology of the immune system. Candidates should have a strong record of research accomplishments in this area. Exceptional individuals at a more senior level will also be considered. Please submit a curriculum vitae, including a description of research goals, and the names of three individuals who can supply letters of recommendation to: Molecular Immunology Search Committee, Rosenstiel Center, Brandeis University, Post Office Box 9110, Waltham, MA 02254-9110, but June 15, 1989. *Brandeis University is an Equal Opportunity/Affirmative Action Employer.*

# Toxicology

## Associate Director, Clinical Toxicology & Safety Evaluation

Smith Kline & French, a leader in Pharmaceutical research, is consolidating and expanding its Safety Assessment Departments. The Department of Toxicology is seeking an experienced senior scientist for the position of Associate Director. This individual will provide scientific leadership and management for two expanding groups of scientists and technicians engaged in clinical and pharmacological evaluations of novel therapeutic agents in animals.

The successful candidate will participate with multi-disciplinary teams in drug discovery and development and will have responsibility for designing and conducting studies to define the toxicologic profile of novel therapeutic agents. The incumbent also would manage a group responsible for evaluating the pharmacologic and physiologic effects of therapeutic candidates on major organ system function and relating those effects to the overall determination of safety.

Candidates with a DVM or MD and a Ph.D. in pharmacology, physiology or toxicology would be ideally qualified for this position. A proven record of accomplishment in experimental and/or clinical research in one of the above areas is required. The successful candidate may be currently employed in an academic or research institution but experience in the Pharmaceutical industry would be advantageous. Board certification in internal medicine would be desirable.

Based in a modern research facility in suburban Philadelphia near Valley Forge, PA, SK&F provides excellent opportunities for innovative, interdisciplinary research in a stimulating and challenging scientific environment. Attendance at national and international scientific meetings is supported and presentation and publication of scientific work is strongly encouraged. We offer an attractive compensation/benefits and relocation package. For confidential consideration, please forward your C.V. and names of three references to Elizabeth McKendry, L0051, Associate Employment Administrator, Smith Kline & French Laboratories, Research & Development, P.O. 1539, King of Prussia, PA 19406-0939. *Equal Opportunity Employer, M/F/H/V.*

## HANS SELYE SYMPOSIA ON NEUROENDOCRINOLOGY AND STRESS: NEUROENDOCRINOLOGY OF GASTROINTESTINAL ULCERATION

September 13-15, 1989

Estérel (near Montreal), Quebec, Canada

The "Hans Selye Symposia on Neuroendocrinology and Stress" are held every 2-3 years and are devoted to specific topics in fields related to neuroendocrinology and stress. The next meeting will be devoted to the neuroendocrine aspects of gastrointestinal (GI) ulceration. The *format* of the meeting will be that of mini-symposia where following 2-3 invited lecturers, brief presentations will be scheduled selected from submitted abstracts. The *topics* to be covered are the neuroendocrine control of gastroduodenal secretion, GI motility, GI microcirculation, gastric and duodenal ulceration, ulcerative colitis, as well as central vs. peripheral neuroendocrine factors in ulcer disease, growth factors and immunology as related to neuroendocrinologic aspects of GI ulceration. *Deadline* for submission of abstracts is May 1, 1989 and for registration to participate without abstract presentation is August 15, 1989. The abstracts will be published in Digestive Diseases and Sciences. Registration material and abstract forms can be obtained from Joyce M. Fried, Brain Research Institute, University of California, Center for the Health Sciences, Los Angeles, CA 90024-1761. Telephone: (213) 825-5061, FAX (213) 206-5855.

The Standing Committee of the Hans Selye Foundation: Mark Cantin (Montreal), Louise Drevet-Selye (Montreal), Sandor Szabo, coordinating chairperson for this meeting (Boston) and Yvette Taché (Los Angeles).

## THE BIOMEDICAL RESEARCH CENTRE

### POST-DOCTORAL AND GRADUATE STUDIES OPPORTUNITIES

The Biomedical Research Centre (BRC) is located on the campus of The University of British Columbia. Research at The BRC focuses on the regulatory mechanisms of cellular growth and differentiation, with a particular emphasis on the roles of cytokines, receptors and post-receptor signal transduction. The facility is equipped for molecular and cellular biology, as well as protein purification, and automated sequencing and chemical synthesis of proteins. Current research areas include: the molecular regulation of steady-state lymphopoiesis and hemopoiesis; the roles of cytokines in autoimmune diseases, infection and tumorigenesis; immunological tolerance and models of human disease using transgenic animals, retroviral gene transfer and homologous recombination; structure-function analysis of the polypeptide and carbohydrate moieties of the lymphokines IL-3 and GM-CSF and their receptors; and the molecular and functional characterisation of cell cycle-regulated protein kinases. The cross-disciplinary exchange of ideas and expertise within its interactive environment makes The BRC ideal for career development.

APPLICANTS SHOULD SEND THEIR CURRICULUM VITAE, A COPY OF RECENT TRANSCRIPTS AND NAMES OF THREE ACADEMIC REFEREES TO:

**The Director,  
The Biomedical Research Centre,  
2222 Health Sciences Mall,  
The University of British Columbia,  
Vancouver, B.C. CANADA V6T 1W5**

### POSTDOCTORAL RESEARCH DRUG DELIVERY SYSTEMS/ DRUG TARGETING

Postdoctoral positions are available in a laboratory studying biological approaches to drug targeting in cancer therapeutics. Delivery systems include liposomes, polypeptides and oligonucleotides. A background in pharmaceuticals or in cancer pharmacology is desirable. Positions are offered for two years with possibility of renewal. Competitive salaries. Please submit a curriculum vitae and names of two references to:

**Prof. R. J. Juliano  
Dept. of Pharmacology  
CB# 7365, Fac. Lab. Off. Bldg. 1106  
School of Medicine  
University of North Carolina at Chapel Hill  
Chapel Hill, NC 227599-7365**

UNC-CH is an Affirmative Action/Equal Opportunity Employer.

### POSTDOCTORAL POSITION IN PROTEIN CRYSTALLOGRAPHY

to solve the structures of the GCN4 leucine zipper, yeast nucleoside diphosphokinase or the phage P22 tail spike. Requirements include 2 to 3 years of experience with data collection, computing, phase determination, structure analysis and graphics. Send c.v. and letters of reference to Tom Alber, Department of Biochemistry, University of Utah School of Medicine, Salt Lake City, Utah 84132. *The University of Utah is an equal opportunity/affirmative action employer.*

### TWO POSTDOCTORAL POSITIONS

available 1 July 1989. One position involves the investigation of cytoplasmic factors regulating DNA synthesis in lymphocytes. The second involves mechanisms of tumor cell adhesion to endothelial and parenchymal cells and regulation of this interaction of cytokines. Experience in molecular biology, biochemistry, and/or protein purification is desired; knowledge of immunology would be helpful. Send curriculum vitae, statement of interests, and names and addresses of three references: Dr. Stanley Cohen, Department of Pathology, Hahnemann University, Broad and Vine Streets, M.S. 435, Philadelphia, PA 19102-1192.

### POSTDOCTORAL POSITION Molecular Neurobiology

Available immediately to study the structures and functions of synapse-specific proteins using molecular cloning, protein chemistry and cell biology techniques. Send Curriculum Vitae and names of three references to: Dr. Thomas C. Südhof, Howard Hughes Medical Institute, Department of Molecular Genetics, UT Southwestern Medical Center Dallas, 5323 Harry Hines Blvd., Dallas, TX 75235-9050, USA.

There is

INTERNATIONAL WEEKLY JOURNAL OF SCIENCE

## MASSEY UNIVERSITY

Palmerston North, New Zealand  
POSTDOCTORAL RESEARCH  
FELLOWSHIPS(36176) Filamentous Fungal  
Genetics

The successful applicant will join a research programme in the Department of Microbiology and Genetics aimed at developing transformation and gene replacement techniques in the ryegrass endophyte *Acremonium loliae*. The position will be available for up to two years. Applicants should have a PhD in an appropriate discipline with experience in Molecular Genetics or Biochemistry. A background in filamentous fungal genetics would be an advantage. Further information may be obtained from Professor D B Scott (tel (063) 69 099 ext. 7965 or Fax (063) 62 140).

Closing date: 30 April 1989.

(36177) Animal Science  
Department

A postdoctoral position is available in the Department of Animal Science, supervised by Drs H T Blair and S N McCutcheon, to conduct physiological studies of the regulation of seasonal wool growth in Romney sheep. This project, which is part of a collaborative research programme, will investigate the physiological mechanisms by which genetic variation in seasonality of wool growth (particularly the winter decline) is expressed. Studies will be based on the University fleece-weight selection lines which exhibit marked genetic variation in seasonality. Applicants should be experienced in the study of whole body and/or tissue metabolism, particularly as it relates to utilisation of amino acids for wool growth and/or endocrine regulation of wool growth. The Fellowship is tenable for a maximum period of two years.

Closing date: 12 May 1989.

Salary: NZ\$35,000 per annum.

Applications, including a full curriculum vitae and naming three referees, should be sent to Mrs V B Bretherton, Personnel Section, Massey University, Palmerston North, New Zealand by the appropriate closing date. (W6012)E

## SANDOZ INSTITUTE FOR MEDICAL RESEARCH

The Sandoz Institute, comprising about 60 staff, is engaged in research on neurobiological problems relevant to the development of novel analgesic drugs. The Institute has a strong commitment to basic

research on the mechanisms of sensory transduction processes and occupies well equipped laboratories within the precincts of University College London, with which it has close academic links.

## TWO POST-DOCTORAL FELLOWSHIPS IN

# 1. Cellular Electrophysiology

## 2. Intracellular Calcium Signalling

These positions form part of an integrated, multidisciplinary study of the actions of neurotransmitters and chemical mediators on sensory neurones and the involvement of second messengers in sensory transduction. The investigations would involve the use of:

1. whole cell and single channel recording techniques and
2. calcium indicator dyes to measure intracellular calcium in single cells.

Salary will be in the range £14,000 - £17,000, depending on age and experience. Applications, which should include a resumé of research to date, plus the names of two referees should be sent to

Mrs M.-C. Stuart, Sandoz Institute for Medical Research, 5 Gower Place, London WC1E 6BN

by Monday 24th April 1989.

## GOVERNMENT OF NEW ZEALAND CAPTAIN JAMES COOK RESEARCH FELLOWSHIP

### ADMINISTERED BY THE ROYAL SOCIETY OF NEW ZEALAND

To commemorate the 1969 bicentenary of Captain Cook's first landing in New Zealand on 9 October 1769 the New Zealand Government established an international research fellowship to perpetuate Captain Cook's spirit of scientific enquiry and exploration in New Zealand and the South-West Pacific.

The fellowship is awarded to one person of senior status for two years (extendable to three) to carry out research within New Zealand or the South-West Pacific region in any appropriate field such as the following subjects (taken in their broadest sense) or in any other relevant field:

**Anthropology**  
**Biology**  
**Geography**  
**Geology**

**Geophysics**  
**History**  
**Medicine**  
**Oceanography**

The successful applicant typically would have at least 5 years post-doctoral experience, have published results of original research and be between 30 and 50 years old. All applicants must have a good working knowledge of English. The successful applicant will be based at a New Zealand university or research institution. The salary will be up to the maximum for an associate professor in New Zealand universities (within the range NZ\$63,800-NZ\$72,000 per annum). A travel grant will be paid equivalent to economy air fare to and from New Zealand for the fellow, spouse and dependent children under 16, plus an allowance for the transport of limited personal effects. Reasonable travel expenses incurred in connection with the research will also be paid.

The successful applicant will be expected to take up the fellowship within six months of appointment in September 1989.

**Applications closing 30 June 1989** are invited for the eighth Captain James Cook Fellowship to be taken up in early 1990. Fellowship brochures and application forms may be obtained from any New Zealand Embassy or High Commission or from the Royal Society of New Zealand, Box 598, Wellington, New Zealand.

(W6009)E

## THE MORRISON MEMORIAL POSTDOCTORAL FELLOWSHIP

The Department of Biochemistry, St. Jude Children's Research Hospital, is enlarging its research efforts in the area of the molecular and cellular biology of signal transduction. As part of this expansion, the Board of Governors has established a memorial fellowship in honor of Dr. Martin Morrison, the founding chairman of the Department. The research programs within the Department are well equipped and offer recent Ph.D. or M.D. graduates the opportunity to participate in energetic, multidisciplinary groups dealing with a range of basic and clinically oriented research. Current research programs within the Department include:

- W.Y. Cheung: Regulatory properties and biological functions of calmodulin;  $\text{Ca}^{2+}$  regulated enzymes.
- J. Cleveland: Growth factor regulation of gene transcription.
- V.A. Fried: The ubiquitin system and post-translational regulatory pathways.
- J.N. Ihle: Mechanisms of hematopoietic stem cell growth regulation, differentiation and transformation.
- S. Jackowski: Regulation of phospholipid metabolism and the production of lipid-derived second messengers.
- C. Rock: Hormone and growth factor stimulated phospholipase C.
- E. Thomas: Antimicrobial and antitumor mechanisms of leukocytes.

Applicants should submit a brief statement of their research interests, curriculum vitae, reprints and names of three references to:

**The Morrison Postdoctoral Fellowship**  
**Department of Biochemistry**  
**St. Jude Children's Research Hospital**  
**332 N. Lauderdale**  
**Memphis, TN 38101**

## STUDENTSHIPS

### ANIMAL HEALTH TRUST Department of Comparative Physiology Balaton Lodge, Newmarket, Suffolk

Applications are invited for a

### PhD STUDENTSHIP

(£7,000 pa) tenable for 3 to 4 years commencing October 1989. Applicants should have, or expect to obtain, a First or Upper Second Class Honours degree in biochemistry or a related discipline.

The research will be undertaken in a Department actively involved in investigating various aspects of exercise physiology and biochemistry of the racehorse. The specific project will be concerned with factors influencing ascorbic acid status in the exercising horse.

*Application forms can be obtained from*  
**C G Cook, Personnel Officer**  
**Animal Health Trust, P O Box 5**  
**Newmarket, Suffolk CB8 7DW**

*Informal enquiries may be addressed to*  
**Dr D Snow (tel: 0638) 661111**

Closing date for applications: 28 April 1989. (8852)F

## UNIVERSITY OF DUNDEE DEPARTMENT OF ANATOMY & PHYSIOLOGY MRC POSTGRADUATE STUDENTSHIP WITH BURSARY

An earmarked Studentship has been awarded to Professor M J Rennie who directs a group investigating fundamental and clinical aspects of fuel and amino acid metabolism in health and disease. The work is currently supported by MRC, SERC and major charities such as Action Research, British Diabetic Association and The Wellcome Trust by awards of about £150K p.a. Applications are invited from prospective graduates (2i degree expected) in any area of the life sciences, chemistry or physics. The project will involve expression of mRNA for mammalian amino acid transporters in *Xenopus* oocytes with the aim of obtaining information about the molecular mechanisms of amino acid transport and cloning the transporter molecules. A bursary of £250-£500 will be added to the first year stipend, according to class of degree awarded.

Studentships or Research Assistantships may be available in other fields; details may be had on application.

The Department has excellent facilities for research and has recently been awarded £900K for refurbishing additional accommodation. Dundee offers outstanding value for accommodation and access to outdoor recreation, within a friendly community.

Applications (with full c.v. and names and addresses of two referees) as soon as possible to **PROFESSOR M J RENNIE, DEPARTMENT OF ANATOMY & PHYSIOLOGY, THE UNIVERSITY, DUNDEE DD1 4HN (Tel 0382 23181 ext 4572)** who will provide a copy of the Departmental Booklet and information about Tayside. Travel and accommodation expenses will be paid for applicants invited for interview. (8873)F

## DEPARTMENT OF BIOCHEMISTRY UNIVERSITY OF OXFORD

### MRC IMMUNOCHEMISTRY UNIT RESEARCH STUDENTSHIP

Applications are invited for a MRC Research Studentship tenable for 3 years, commencing October 1989, to work towards a D.Phil. degree with Dr. S.K.A. Law on the Molecular Biology of the Complement Receptor Type III. The project will focus on the expression of a soluble form of the antigen and the characterization of its higher order structure. It will involve the use of techniques in recombinant DNA and protein chemistry.

Candidates should have, or expect to obtain, a first or upper second class honours degree in one of the biological science disciplines.

Applications, including a complete CV and the names and addresses of two referees, should be sent to the Director, MRC Immunochemistry Unit, by 15th May, 1989. (8880)F

DEPT OF BIOCHEMISTRY, SOUTH PARKS ROAD, OXFORD, OX1 3QU.

### ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London) Rowland Hill Street London NW3 2PF

### Ph.D. RESEARCH STUDENTSHIP

Applications are invited from candidates wishing to pursue a full-time three year Ph.D. programme of investigation into the relationship between Mobility, Functional Ability and Physical Training in Old Age. BSc. Hons. (1st or Upper 2nd Class) or MSc. sought from Physiology, Physiotherapy or Occupational Therapy.

Informal enquiries to **Dr. C. A. Greig, Academic Department of Geriatric Medicine (01-794-0500 x4351)** to whom applications, including a c.v. and names and addresses of two referees should be sent by 24 April 1989. (8843)F

# ESCHERICHIA COLI AND SALMONELLA TYPHIMURIUM

CELLULAR AND MOLECULAR BIOLOGY

Editor in Chief: Frederick C. Neidhardt

Editors: John L. Ingraham, K. Brooks Low, Boris Magasanik,  
Moselio Schaechter, and H. Edwin Umbarger

## From the Review in Nature:

"The objective of these two volumes, in the words of the editors, is to provide for the first time a comprehensive treatment of the molecular and cellular biology of *Escherichia coli* and *Salmonella typhimurium* that would be a logical first resource for anyone seeking information about these organisms. With few reservations we think that this objective has been achieved, and achieved at a price for the flexicover edition that makes the books an exceptional bargain.

The two volumes are divided into six parts, with a total of 104 chapters written by about 150 authors who are recognized authorities. The total number of literature citations must be nearly 20,000. Despite these encyclopaedic dimensions and its multi-author make-up, the treatise is remarkably free from the overlap and the imbalance that frequently mars this kind of enterprise. It

is equally pleasing to be able to report that the majority of authors have succeeded in writing what their editors required of them: "thoughtful and narrative reviews" as opposed to mere compilations of data and references. . . . Overall we and other colleagues are very impressed by these books. . . . The editors have obviously put a lot of effort into this enterprise and played an effective disciplinary role in maintaining breadth without overlap, and a uniform style. There is nothing comparable available on the market and everyone working with, or teaching about, *E. coli* and *S. typhimurium* will find these books to be invaluable. Final year undergraduates and postgraduate students will also find them an excellent resource."

B. M. Wilkins and R. H. Pritchard, *Nature*

### CONDENSED CONTENTS

#### Volume I

##### Part I. MOLECULAR ARCHITECTURE AND ASSEMBLY OF CELL PARTS (9 chapters)

##### Part II. METABOLISM AND GENERAL PHYSIOLOGY

##### A. Class I Reactions: Generation of Precursor Metabolites and Energy (9 chapters)

##### B. Class II Reactions: Conversion of Precursor Metabolites to Small-Molecule Building Blocks (19 chapters)

##### C. Class III Reactions: Formation and Processing of Polymers (10 chapters)

##### D. Utilization of Energy for Cell Activities (4 chapters)

#### Volume II

##### Part III. GENOME AND GENETICS

##### A. The Genome (6 chapters)

##### B. Alterations in the Genome (5 chapters)

##### C. Gene Transfer: Conjugation (4 chapters)

##### D. Gene Transfer: Transduction (2 chapters)

##### E. Gene Transfer: Transformation (1 chapter)

##### F. Genetic Measures of Chromosome Size (1 chapter)

##### G. Strains and Useful Strain Constructions (3 chapters)

##### Part IV. REGULATION OF GENE EXPRESSION

##### A. General Mechanisms (5 chapters)

##### B. Regulation of Multigene Systems (8 chapters)

##### C. Paradigms of Operon Regulation (8 chapters)

##### Part V. GROWTH OF CELLS AND CULTURES (6 chapters)

##### Part VI. ECOLOGY, EVOLUTION, AND POPULATION STRUCTURE (3 chapters)

# Catch your glycoproteins!

## Glycan Detection Kit from Boehringer Mannheim

The new DIGOXIGENIN based carbohydrate immunodetection system guarantees you:

- ◆ **High specificity:**  
only glycoconjugates are detected
- ◆ **High sensitivity:**  
as few as 10 ng of glycoprotein is easily detected
- ◆ **Fast performance:**  
less than one working day is needed

For further details on this kit please ask your local representative or

# SCIENCE NEEDS SCIENCE

SINCE THE ADVENT OF THE HOURGLASS, SCIENTIFIC CREATIVITY HAS CONCENTRATED ON FINDING NEW WAYS OF SAVING TIME AND INCREASING RELIABILITY IN ALL FIELDS.

THE MOST RECENT SCIENTIFIC DISCOVERIES HAVE ALWAYS BEEN APPLIED TO DEVELOPING MORE ACCURATE AND RELIABLE RESEARCH TOOLS, WHICH IN TURN WILL PROMOTE SCIENTIFIC PROGRESS.

FOR OVER 30 YEARS, IN THE CONTINUING TRANSFER BETWEEN RESEARCH AND TECHNOLOGY BIO-RAD HAS BUILT ITS REPUTATION THROUGH:

- ◊ THE DESIGN, MANUFACTURE AND MARKETING OF INNOVATIVE SYSTEMS
- ◊ THE HIGH RELIABILITY OF ITS PRODUCTS ACKNOWLEDGED BY THE SCIENTIFIC COMMUNITY

BIO-RAD IS ACTIVE IN 6 MAJOR DISCIPLINES OF SCIENTIFIC AND MEDICAL RESEARCH:

- ◊ FINE BIOCHEMICALS
- ◊ CHROMATOGRAPHY & ELECTROPHORESIS
- ◊ CLINICAL DIAGNOSTICS
- ◊ CONFOCAL LASER MICROSCOPY
- ◊ SEMICONDUCTOR MEASUREMENT SYSTEMS
- ◊ FOURIER TRANSFORM INFRARED SPECTROMETERS

# The switch is on to fast flow

To Q Sepharose® Fast Flow and S Sepharose® Fast Flow for preparative ion exchange chromatography. Why? Resolution. Speed. Capacity. Easy scale up.

The excellent resolution of Q and S Sepharose FF has made them standards in the purification of proteins. Strong ion exchange groups let you work at the pH most appropriate to your separation. And when speed is critical, the outstanding flow properties of Q and S Sepharose FF give you a faster separation – up to 400 cm/h.

The very high capacity of Q and S Sepharose FF means that you can load plenty of material in every run. Load up to 12 g of HSA on a 100 ml column packed with Q Sepharose FF and up to 5 g of IgG on a 100 ml column packed with S Sepharose FF.

Or you can optimize your separation on Mono Q® or Mono S® with FPLC® System. Then scale up to a preparative purification on Q or S Sepharose FF by simply varying flow rate and gradient volume. And if you are moving up to large scale separation, you won't find a better starting point than Q and S Sepharose FF.

Four reasons. Resolution. Speed. Capacity. Easy scale up.

Are you ready to switch to the superior ion exchange media? Contact Pharmacia LKB today and we'll send you all you need to make your decision about Q and S Sepharose Fast Flow.

# THE NUMBER 1 REASON TO CHOOSE THE ACUGEN™ PERSONAL DNA SEQUENCER™

## #1. EASY TO USE:

Forget autoradiography. Forget reading autoradiograms. Sensitive beta detectors gather data from the gel as it's running and convert that data to DNA sequence. And the gel system is fast, accurate, and easier than any you've ever used.

## #1. AFFORDABLE:

The Acugen 402 costs less than half as much as other sequencers. So even if you're a small lab, you can afford it. And if you're a larger lab, you'll probably want to keep several running. The Acugen 402 is a personal sequencer—at a personal price.

## #1. <sup>32</sup>P DETECTION:

The Acugen 402 builds on success—the success of reliable, inexpensive <sup>32</sup>P reagents and standardized, widely used protocols. There are no new complicated techniques to master. All you'll have to get used to, is how fast you can generate DNA sequencing data.

## #1. COMPACT:

The Acugen 402 takes up remarkably little bench space—about as much as a manual sequencing apparatus. Yet it brings you all the power of DNA sequencing automation. Big features. Small size. The Acugen 402 is the ultimate combination.

For more information or a complete in-lab demonstration of the Acugen 402 personal sequencer, call us at 1-508-650-1180. We'll show you why we're one up on every other sequencer.

Amplify your DNA with new AmpliTaq  
from Perkin-Elmer Cetus.

The new AmpliTaq™ Recombinant DNA Polymerase is a superior genetically engineered enzyme offering key advantages in the patented\* GeneAmp™ Polymerase Chain Reaction (PCR) technique including:

- ☐ A purer DNA polymerase by using state-of-the-art recombinant DNA production techniques
- ☐ The elimination of unwanted thermostable nucleases since the enzyme is not purified from a thermostable bacterium

Extensive studies have shown that the thermostability and specificity of the recombinant enzyme is similar to the native enzyme and can be substi-

tuted for native *Taq* DNA Polymerase for most PCR applications and DNA sequencing.

The new AmpliTaq DNA Polymerase is also available in the GeneAmp DNA Amplification Reagent Kit which has been optimized for the DNA Thermal Cycler – an instrument specifically designed for automating the temperature cycling required in the PCR process.

AmpliTaq™ and GeneAmp™ are trademarks of the Cetus Corporation  
IsoPure™ is a trademark of the Perkin-Elmer Corporation  
\*PCR is covered by US Patent No. 4,683,202 issued to Cetus Corporation.

6 April 1989

Vol. 338 Issue no. 6215

Noctilucent ice clouds, first reported in 1885, may be a result of the increasing level of atmospheric methane, page 490. The cover photograph was taken at Kustavi in Finland on 3–4 August 1986 by Pekka Parviainen 2 s exposure, 50 mm lens, (f/1.4 on Kodachrome KR 64.)

## THIS WEEK

### Light-weight tweezers

The recently developed 'optical tweezers' use the force exerted by light to manipulate small objects, such as intact cells. Optical tweezers have now been used to investigate the elastic properties of bacterial flagella, page 514.

### Exhaust clean-up

Automotive engineers are working on ways to cut emissions of nitrogen oxides from the internal combustion engine. But in one promising system, the oxygen also emitted during combustion limits efficacy, page 492.

### Electrophoresis gels

Observations of individual DNA molecules during gel electrophoresis by fluorescence microscopy should lead to insights into the basis of this much used, but poorly understood technique. Pages 520 and 461.

### Metals in the making

Deep beneath the East China Sea, hydrothermal vents are in the process of forming the 'Jade deposit', a modern-day analogue of the Kuroko-type sulphide deposits rich in the metals zinc, lead, copper, gold and silver. Page 496.

### Samoaan odyssey

In a new film, Derek Freeman continues his critique of Margaret Mead's anthropological work in Samoa. Adam Kuper looks at on both the film and the wider issues. Commentary, page 453.

### Fractal earthquakes

Theories of chaos, developed in diverse fields, are being brought to bear on studies of the destructive forces of plate tectonics. Page 459.

## Torso a receptor?

The torso gene in *Drosophila* is the archetype of one of three classes of genes that specify the anterior-posterior axis of the embryo during oogenesis. Sequencing of the gene shows that its product is likely to be a transmembrane protein with an intracellular tyrosine kinase domain, page 478.

## Mars bar

On page 487, the effects of meteoritic impacts are proposed as a mechanism that explains the loss of atmosphere on Mars. The model predicts a primordial martian atmospheric pressure of about one bar, or one (Earth) atmosphere. On the same basis Earth's primordial atmosphere would have been about six times today's value. See also News and Views, page 465.

## Educating T-cells

Tests of the ability of isolated epithelial cells to present antigen suggest that their major histocompatibility complex molecules differ from those on other tissues, binding a broad spectrum of T-cell receptors and thus offering a basis for selection of thymocytes biased towards recognition of self-MHC plus antigen. Page 503.

## Muscular dystrophy

Using the polymerase chain reaction, eight different forms of dystrophin have now been detected, with differing tissue distribution. Page 509.

## Ageing challenge

The case for slowing of the ageing process and disease by dietary restriction is presented in a new book reviewed by Alex Comfort, page 469.

# Change Your Mind...

ABOUT PLASMID PREPS

**FORGET...** 1 liter cultures

**THINK SMALL...** small volume cultures in CIRCLEGROW high density growth medium.

**FORGET...** enzyme digestions and organic extractions

**THINK SIMPLE...** isolate plasmid DNA without lysozyme, protease or RNase digestions; phenol or chloroform extractions.

**FORGET...** extended CsCl/EtBr isopycnic spins and...

**THINK FAST...** less than 90 minutes from cell pellet to purified plasmid DNA.

Think about it... Why expend the time and effort to isolate a milligram of plasmid DNA when you really need less than 5% of that amount for most cloning projects... Especially now that the CIRCLEPREP KIT allows you to get enough DNA to do what needs to be done quickly... 90 minutes from cell pellet to purified plasmid DNA... 50 to 100 ug of substrate-quality plasmid DNA that will cut and ligate every time... Think about it... but don't think too long.

# CIRCLEPREP™

## RAPID PLASMID DNA PURIFICATION KIT

Isolate preparative quantities of enzyme substrate-quality plasmid DNA in 90 minutes.

patent pending

60 MINUTES

CLEARED  
LYSATE

### CIRCLEPREP Kit, cat. #CP100

Kit contains all reagents necessary to grow cells, prepare cleared lysate and purify preparative quantities of enzyme substrate-quality plasmid DNA.

20 plasmid preps per Kit each typically yielding 50 ug of enzyme substrate-quality plasmid DNA per prep.

the DNA sequencing experts...

# TAQUENCE™

## THE FINEST *Taq* DNA SEQUENCING SYSTEM FEATURING CLONED *Taq*

- Includes the only, and highest purity, cloned *Taq* DNA Polymerase

- Sequences at temperatures over 70°C

- The only kit which includes both dGTP and 7-deaza-dGTP to eliminate compressions

- A novel and more efficient protocol

To complement the revolutionary Sequenase® sequencing system, USB, the only company to offer the full range of sequencing products, introduces TAQUENCE™. This kit is a highly efficient DNA sequencing system using the *only*, and highest purity, cloned *Taq* Polymerase. For those who require the benefits of sequencing with *Taq*, now USB offers TAQUENCE™.

The TAQUENCE™ sequencing protocol makes efficient use of cloned *Taq* polymerase and nucleotide analogs (7-deaza-dGTP and [ $\alpha$ -<sup>35</sup>S]dATP) to generate high-resolution sequencing ladders at reaction temperatures over 70°C, even from compression-prone DNAs.

TAQUENCE™ Features:

- Use either [ $\alpha$ -<sup>32</sup>P] or [ $\alpha$ -<sup>35</sup>S]dATP

- For M13, pUC and similar vectors

- Universal (-40) primer

- Reagents for 100 Sequences

- Complete protocol book

- Supported by the finest, most experienced DNA sequencing scientists

Whatever your requirements, only USB can serve all your sequencing needs.

71060

**Figure 1**

**Figure 2**

**Figure 1.** Sequence of M13mp7 — This well-known vector contains a large, G/C rich region of dyad symmetry. *Taq* DNA polymerase and 7-deaza-dGTP generate an easily-readable sequence of this region.

**Figure 2.** Sequence of M13mp18 — Note that sequence ranges from close to the primer to more than 800 bases, with uniform band intensities. This sequence was run using 7-deaza-dGTP.

# The natural alternative to radioactive labelling

Boehringer Mannheim have developed a brilliant new non-radioactive DNA labelling and detection kit which is:

- **Safe** – no problems with exposure to radioactivity, containment or disposal
- **Sensitive** – for single copy gene detection
- **Visual** – with low background and excellent signal to noise ratios
- **Economical** – probes are stable for 12 months or more
- **Rapid** – visualisation begins within minutes
- **Convenient** – the kit contains all essential reagents for labelling and detection

... the natural choice for your lab

# Highest resolution of chromosomal DNA

## New CHEF-DR™ II System: A major advance in pulsed field electrophoresis.

Yeast chromosomes, strain  
YNN 295. 16 chromosomal DNA  
fragments are resolved. Sizes  
range from 0.2 to 2.2 megabases.

**T**he CHEF-DR II system\* lets you resolve DNAs from 200 bases to 10,000,000 or more,<sup>1</sup> with sharp bands. This powerful system integrates advanced micro-electronics and electrophoresis technologies to produce straight lanes and an extraordinarily wide range of size separations.

The CHEF-DR II system is the only system available with electronic feedback clamping of each of the chamber's electrodes. The voltage sensing provides uniform fields in the gel at all times, independent of variations in buffer conductivity,

sample placement, gel dimensions, or temperature. Consequently, you obtain all the following benefits:

- Highest resolution
- Straight lanes
- Sharp bands
- High sample capacity, up to 30 lanes
- Widest range of DNA size separation
- Reproducible separations

A lot more than equipment comes with the CHEF-DR II system. The comprehensive instruction manual guides you through sample preparation and electrophoresis. We've

also included strategies for separating all sizes of DNA. And we also provide in-depth technical support after you begin your pulsed field experiments.

The CHEF-DR II system can extend your horizons in chromosome analysis, mapping, screening, and DNA sizing. Bulletin 1430 brings you complete details, including a comparison of pulsed field techniques and their respective resolving powers.

\*Dynamically Regulated Clamped Homogeneous Electric Fields. Patent applied for.

Lowest Prices in Europe:

# **\$6 per base High Quality DNA Express Service**

**MedProbe A.S., European Distributor for Genetic Designs, Inc., can offer the most comprehensive and convenient service available for high quality polynucleotides, at lowest prices and with express delivery that even in-house services cannot match.**

MedProbe A.S. is formed by a group of Norwegian scientists working with recombinant DNA technology at Rikshospitalet (The National Hospital) and The Norwegian Radium Hospital, Oslo, Norway. Our products are synthesized by Genetic Designs, Inc., utilizing the highest technology available, developed at Baylor College of Medicine, Houston, Texas.

## **Quality**

Electrophoretic analysis is provided with each custom DNA.

## **Fast Service**

Products are guaranteed to be shipped within 10 working days; an express service (5 working days) is also available.

## **Order by telefax, mail, or telephone**

### **Custom Polynucleotide Service (Prices in U.S. \$)**

Setup .....	\$40
Synthesis (0.2 micromole scale; min. 5 A <sub>260</sub> unpurified, min. 1 A <sub>260</sub> gel purified) .....	\$6 per base
Redundancies (wobbles) .....	\$6 per base

# CONTROL OF FULLY PROGRAMMABLE DRI-BLOCK

CYCLES PHC-2

This latest programmable Dri-Block® temperature cycler PHC-2 has a powerful microprocessor programming capability yet is designed for simplicity of operation. It is now possible to link programmes, hold temperatures for long periods choose four ramp rates up and down and recall temperatures and times from the PHC-2 memory. Two models are available for use with either 0.5 ml or 1.5 ml microcentrifuge tubes.

- Temperature range 0°C–99°C
- Fast temperature change
- Wide and variable number of segments, programmes and cycles – limited only by memory capacity.
- Four user selectable up/down ramp rates
- 99 hour maximum hold time
- Remote sensor in dummy tube to read sample temperature and initiate programme timing.
- Block uniformity 3°C
- RS232 outlet/centronics printer output
- 54×0.5 ml or 24×1.5 ml microcentrifuge tubes
- Water cooled with separate connection for end of programme below ambient cooling
- Temperatures and times held in memory for recall to screen or printer

## PHC-1

For less sophisticated programming requirements the alternative model PHC-1 is a simple to use heat/cool unit providing a repeatable cycle of up to three independent temperatures and dwell times. A standard aluminium block will accept up to 54×0.5 ml capped microcentrifuge tubes.

*"...a major breakthrough in the field of molecular biology..."* —SIM News

*"It is having a revolutionary impact."* —H.H. Kazazian, Johns Hopkins University

### PCR TECHNOLOGY Principles and Applications for DNA Amplification

Edited by Henry Erlich, PhD, Senior Scientist and Director of Human Genetics, Cetus Corporation  
 PCR (Polymerase Chain Reaction) technology is a revolutionary technique which enables scientists to rapidly generate large amounts of genetic material from a slight trace which would otherwise be too small to analyze. With applications in both research and diagnostics, PCR will soon become a standard procedure in biotechnology and medical diagnostic laboratories. *PCR Technology: Principles and Applications for DNA Amplification* is an introduction and guide to the technology. Written by the pioneers in the field, this is the authoritative publication detailing the methodology and the wide range of applications of PCR technology, including medicine, evolution and forensics.

#### Projected contents: INTRODUCTION TO THE PCR

History of PCR Development—Brief Essay • Description of the PCR Method—Basic Principles and Properties of the PCR • Thermostable DNA Polymerases • Automation • Sample Preparation

#### RESEARCH APPLICATIONS—BRIEF OVERVIEW

Direct Sequencing Using PCR • Preparation of Specific DNA Fragments Using PCR • Detection of Gene Expression • Genetic Mapping Using PCR Amplification of Individual Gametes

#### DIAGNOSTIC APPLICATIONS—BRIEF OVERVIEW

Detection of Pathogens • Diagnosis of Monogenic Genetic Diseases • HLA DNA Typing and Disease Susceptibility • Forensic Applications • Detection of Activated Oncogenes • Future Developments and Applications—Brief Essay

March 1989, approx. 176 pp., softcover 0-935859-56-X \$19.95

## London to Switzerland. Guess who flies at peak times?

Whenever business calls on you to visit Switzerland, you can always call on Swissair to fly you there (and back) at a civilised hour.

So, for example, early flights from London, Birmingham or Manchester are timed so that you'll get to Zurich ready for a good day's work.

Then, convenient return flights mean that you'll be back in time for a relaxed evening at home. (After Swissair's award-winning cuisine and in-flight service, that shouldn't be too difficult.)

Because, not only do we fly at peak times, we also have the highest standards.

**swissair**   
**How very civilised.**

Heathrow to Geneva, Zurich and Basle, Birmingham and Manchester to Zurich.

# BACTERIORHODOPSIN NOW AVAILABLE

Bacteriorhodopsin is isolated from  
**Halobacterium halobium**  
in the form of purple membranes.

## Delivery form

Membrane fragments ("purple membranes"),  
diameter approx. 1  $\mu\text{m}$ , thickness approx. 4.8 nm,  
a) aqueous suspension

- membrane concentration up to  $\sim 30$  mg/ml
- absorbance  $_{280\text{ nm}}$ /absorbance  $_{560\text{ nm}} = 2.3 \pm 0.2$
- conductivity of the suspension  
     $< 50 \mu\text{S} \cdot \text{cm}^{-1}$ , pH 6-7
- b) lyophilized

## Application

Optical data processing (optical switches,  
holography, information storage),  
nonlinear optics or as light sensors.

## Higher education crisis (cont'd)

Contradictions built into Britain's system of higher education seem to have persuaded the government towards structural change. One ingredient should be freedom — even the freedom for institutions to become extinct.

It is not every day that national higher education systems are augmented by the addition of 25 autonomous institutions, but that is what happened in Britain on 1 April. The provisions in last year's Education Reform Act that replaced the University Grants Committee (UGC) by the untried body called the Universities Funding Council also transferred responsibility for Britain's 25 polytechnics from local education authorities to 25 free-standing boards of governors, whose public support will be channelled through a similar funding council. On the face of things, Britain has for the first time a system of higher education with institutions whose diversity compares with that elsewhere.

This development inevitably marks the beginning of yet another upheaval in British higher education, but one whose consequences cannot be foreseen. But on the face of things, the two sectors of higher education will be differently affected. The universities fear that the new regime will bring even more direct control from the centre: the act gives the government powers to issue general directions to the funding council, which itself has powers to assure itself that the funds which it disburses are spent in ways of which it approves. By contrast, the polytechnics generally welcome the new regime. At the least, they will be rid of the bumbledom of local authority control. Many may even be able to work out for themselves distinctive, even novel, ways of contributing to the higher and professional education of a population increasingly

short of skill. But that is merely how it seems at present. For while the provisions of last year's act are entering into force, the British government seems already to be flirting with even more radical proposals for change.

The self-contradictory decisions of successive governments going back for exactly a quarter of a century (to the then government's enthusiastic endorsement of the Robbins recommendations that the numbers of students in higher education should be increased by a factor of 2.5) have left a hopeless muddle. The decision that the Robbins expansion required the creation of new universities has left Britain with too many universities that are too small justly to claim the title — and which are now being further robbed of academic independence by UGC's otherwise sensible attempts at rationalization.

The decision, just a few years later, that 26 polytechnics (one has since dropped out) should acquire equal status, but be managed differently, may have been most notable as a sign of emerging political animus against the universities, but it created a legacy of division (known as the 'binary system') which even last year's Reform Act left untouched. The same quarter of a century has sanctified the notions that public subventions of universities cover the costs of maintaining a capacity for carrying out research, that eligible students are entitled to maintenance grants (which are nevertheless inadequate for their stated purpose), that tuition fees for home students (now including the EEC) should be way below the economic cost and that academics should be systematically underpaid. Most governments faced with these problems have behaved as if they would prefer to start from somewhere else. The present government, with its reputation for radicalism to preserve, seems now to have woken to the need to cut the knot. After years in which it appeared to be concerned only with the money costs, it now allows that the origins of its difficulties may be structural.

So they are. There is, for example, a glaring contradiction in the university sector between the need that resources should be used effectively and the need that universities should shape the patterns of their own activities. In the first case, UGC prudently, in its last few years, took steps to see that the teaching in fields such as Russian language, agriculture and philosophy should be concentrated at particular universities, chosen (controversially) for their scholarship. A similar reorganization is now under way in the Earth sciences, and there are now pro-

### Computer subscriptions

Even marvellous machines have bugs.

FROM this issue, new arrangements have been made for maintaining and fulfilling subscriptions to *Nature*. Subscriptions in the United States and Canada will be handled by JCI Data Processing Inc. of Delran, New Jersey. For the rest of the world excluding Japan, the maintenance and fulfilment of subscriptions have now been transferred to *Nature's* own computer system equipped with customized VISTA software. While there is every confidence that the end result will be a better service for subscribers, their indulgence for the customary unforeseen problems is earnestly requested. Arrangements for Japan continue unchanged. □

posals that rationalization (as it is called) should be extended to the teaching of physics, chemistry and biology (see *Nature* 338, 363; 30 March 1989). But two foreseen difficulties are now apparent. The cost of reorganization is itself high. And the end-point of the process must be that few British universities will be able to offer a range of studies wide enough to justify their social and academic functions. Is that not a high price to pay for a fudged remedy for mistakes made a quarter of a century ago?

The polytechnics, new-found delight with titular independence notwithstanding, may soon find themselves in a similar case. While their bread-and-butter teaching at the undergraduate level will continue to be supported by their funding council, many of them appear to believe that their future lies in the further development of professional and continuing education, usually of a technical or technological character, for which there is a crying need. More directly than the universities, they will be exploring the now non-existent British market in adult education. The clever among them will no doubt be able to forge profitable links with the network of new technical training councils which the government has separately proposed. But they, too, may then find that the end result is that they have exchanged one kind of thralldom (to local authorities) for another.

The support of research in this changing pattern raises other contradictions. The British research councils make project grants to polytechnics as well as to universities, although the bulk of what they choose to spend in this way ends up in universities. (Part of the explanation is that polytechnic budgets are not reckoned to cover the cost of maintaining research capability, notionally 30 per cent of UGC's recent subventions, which is why they seemed to the Labour government of 1966 to be more "cost-effective".) But since the early 1970s, all the research councils have been spending too great a proportion of their resources on central facilities and too little on research grants, while universities have more recently taken to squirrelling away research money to keep body and soul together. The process has now gone so far that the Science and Engineering Research Council, the largest of the four concerned with science, seems to have put its responsibilities towards individual researchers second after its enthusiasm for directed research (see *Nature* 337, 291; 27 January 1989). So why bother to maintain a capacity for research at universities?

If the British government seriously intends to resolve these issues, it needs some guiding principles. Here is a short list to begin with.

■ **Autonomy.** The British government and its new funding councils must recognize that academic institutions are themselves the most reliable judges of how all kinds of higher education should develop. (Civil servants have a poor track record in this role.) But good judgement requires both the freedom and the size to respond flexibly to changing circumstances. The right to decide what to teach, and how, the cornerstone of academic freedom, is the best guarantor of continuing good sense. Institutions'

dependence on public funds is neither here nor there: the University of California is not noticeably compromised by decisions made by the government of California, which foots the bill. The principle applies as much to the polytechnics as to the universities.

■ **Incentives.** Means must be found of rewarding successful institutions. Much of the present mess in British higher education stems from the way in which institutions have been deprived of a sense of opportunity for close on 20 years. The regulation of capital funds and even of student numbers have been used to constrain the sizes of institutions (keeping too many of them too small). The government should now be prepared to see this relationship turned inside-out. While growth is not everything in academic life, institutions wishing to grow and able to attract the students should be enabled to do so. The other side of that coin is that unsuccessful institutions may shrink, even to the threshold of viability, which may be politically uncomfortable. But how else can a government which believes that market forces discover truth conduct itself?

■ **Research.** Reputation in research is another legitimate goal for academic institutions (and a powerful means by which the quality of its teachers may be generally improved). Research is also, of course, valuable in its own right. But this reward has also, in the past decade, been denied by the scarcity of funds, likely to be further restricted by the research councils' ever-greater fondness for directed research. And in the university sector, there is a prospect that the implicit distribution of research overhead will now be entirely out of pattern with the planned concentration of research. This is why it will seem attractive to the government to arrange for a wholesale transfer of funds of research support in universities from the funding council to the research councils, but that would be a mistake. The more urgent need is to come to a clear decision about the responsibilities of the research councils towards research in both the universities and polytechnics, and then to let institutions of all kinds find their appropriate levels. Less successful institutions may find themselves losing in the competition for survival, but to deny them the opportunity of reversing that trend would be destructive.

■ **Money.** On past form, the British government would probably believe that it had discharged its responsibilities to higher education if it could persuade other people to meet the costs, but the inference is incorrect and the goal absurd. Exhortation will not have British industry or parents supporting higher education the day after tomorrow; even tax incentives on the US pattern would probably have only a small effect (which is no reason for not trying them). But there is a case for changing radically the ways in which funds are at present channelled to institutions. Higher tuition fees (paid for indirectly by central government) are the obvious means by which universities could compete for students and so win back their freedom — even their freedom to go out of business. □

# Cold fusion causes frenzy but lacks confirmation

- Worldwide attempts to reproduce results
- \$5 million may be given for US research

## Washington, Tokyo & London

REMARKABLE reports of "nuclear fusion in a test-tube" achieved by two laboratories in Utah have prompted a frenzy of activity in laboratories around the world as others try to replicate the experiment.

First news of the reported breakthrough in 'cold fusion' came from a press conference on Thursday, 23 March, at the University of Utah in Salt Lake City. Stanley Pons, a professor of chemistry at Utah, and his colleague Martin Fleischmann from the University of Southampton reported that they had achieved fusion by passing a current through a palladium electrode in an electrolyte solution in deuterated water. By the next day, on the basis only of newspaper accounts of the experiment, laboratories around the world were scrambling to copy the experimental design.

At the same time, traffic started flying across computer networks as interested chemists and physicists sought details of the experiment. By the end of last week, preprints of papers prepared for publication by both Pons and a second Utah group, led by Steven E. Jones of Brigham Young University in Provo, were available on electronic bulletin boards.

Numerous laboratories in the United States have attempted to replicate the findings. Los Alamos National Laboratory, Lawrence Livermore National Laboratory, IBM in Yorktown Heights, New York, AT&T Bell Laboratories in New Jersey and the University of Illinois at Champaign-Urbana are just some of the institutions that are said to be looking into the Utah claims, although none has reported unequivocal confirmation. The price of palladium has reached new heights on commodity markets.

Professor Noboru Koyama of the Tokyo University of Agriculture and Chemistry reported at a meeting of the Chemical Society of Japan on 1 April that his team had detected very large amounts of heat and gamma rays in an experiment two days earlier when they passed an electric current between palladium and platinum electrodes in an insulated tube filled with heavy water. However, Japanese experts who have seen Koyama's results expressed scepticism about the validity of the claim because no measurements of neutron yield were made. Koyama says he will try to duplicate the experiment with the Japan Atomic Energy Research Institute to determine neutron yield.

In Britain, teams from the University of

Birmingham and the Rutherford Appleton Laboratory and the UK Atomic Energy Authority at Harwell are attempting to confirm the results, and two scientists at the University of Debrecen in Hungary, Gyula Csikai and Tibor Staricskoi, claim to have obtained the same results as Fleischmann and Pons, but no details of their experiment are yet available.

In Italy, the Ettore Majorana Centre for Scientific Culture has announced a

Pons and Fleischmann: handling it carefully.

world conference for next week (12 April) in Erice to discuss the cold-fusion experiments. Europe, the Soviet Union and the United States are about to launch a ten-year, \$1,000-million project to study the viability of fusion by inertial confinement using X-ray lasers, but all may change pending the conclusions of the conference.

Press interest, as well as interest from the scientific community, remains at a fever pitch. At a seminar last week at the Salt Lake City campus, Pons presented additional details of the experiments to a packed lecture hall. He reported that his laboratory had achieved even greater energy efficiency from the experimental apparatus, although he joked that it would be 100 years before the technology could be made commercially available. Pons warned those trying to replicate the experiment to be extremely careful, as his own early attempts had led to heat generation that had run out of control.

The Brigham Young group has been less forthcoming in public about their results. They believe they are seeing a signal indicating that the deuterium atoms are fusing inside the palladium lattice, although they have not seen the same energy output recorded by Pons and his colleagues.

The US Department of Energy (DoE) has been interested in research in cold fusion for some time. According to a DoE

spokesman, the agency has spent some \$9 million in this field, with \$1.9 million going to Jones. A proposal from Pons submitted last fall for DoE support for a project to "further explore nuclear fusion reactions in deuterium-charged palladium" was approved by DoE's Advanced Energy Projects Division, and \$322,000 is expected to be released for the project later this spring.

The state of Utah has shown even greater enthusiasm. The day after the University of Utah press conference, Governor Norm Bangerter announced he would convene a special session of the state legislature for the sole purpose of considering a supplementary budget request of \$5 million for a new institute to pursue research in cold fusion. National Aeronautics and Space Administrator James Fletcher has agreed to sit on an advisory panel for the new institute once it is created. A spokesman for Bangerter says the new money is contingent upon confirmation of the Pons experiment, but it is unclear whether that will come before the legislature holds its session tomorrow (7 April). □

## AUSTRALIA

### Human embryo experiment banned

#### Sydney

THE state government in Victoria has overturned a decision to permit a controversial experiment on human embryos and one member of the committee to regulate *in vitro* fertilization (IVF) has resigned in protest. The experiment, designed to test human embryos for birth defects before implanting them in patients, would have been the first to involve embryos older than 22 hours. Dr John Henley, who resigned, is a theologian and master of one of Melbourne University's colleges. He has been a member of the Standing Review and Advisory Committee on Fertility, chaired by Monash University's Professor Louis Waller, from its inception.

The experiment was to have been carried out by the IVF research group at Monash University, headed by Dr Alan Trounson. It would have involved the biopsy of 11 embryos that had been slow to grow. Trounson says that the experiment was approved unanimously by the committee. "It even passed without comment from Father Harmon (the representative of the Roman Catholic Church), who is not allowed to approve of anything."

According to Trounson, the government's intervention came in response to public pressure, provoked by newspaper reports saying that the experiment would lead to genetic engineering and cloning. He says that "the government's action is an unfortunate politicization of the whole exercise".

Charles Morgan

## Release of sea-floor maps

### Washington

THE US Navy made a U-turn last week and announced that it will permit the release of most of the detailed sea-floor maps of the US Exclusive Economic Zone (EEZ) prepared by the National Oceanic and Atmospheric Administration (NOAA). The announcement follows rumours that the Navy was steaming in the other direction and was about to condemn all high-resolution bathymetric data collected in federal programmes to the same fate as the NOAA data, classified by a White House memo from Vice Admiral John Poindexter in 1985.

The change in policy comes as a welcome relief to oceanographers who were living "under threat that our data might become classified and that we would not be able to freely distribute our results" according to Ken Macdonald of the Marine Science Institute at the University of California at Santa Barbara. The NOAA maps are likely to be an exciting data source, he said, providing detailed information on many scientifically interesting areas off the west coast.

Restrictions on the NOAA maps will not be lifted for all of the 130,000 square kilometres of sea bed they cover. Excluded will be areas, of yet undefined size, around ballistic missile submarine's home ports. The Navy's own massive collection of high-resolution bathymetric data will definitely remain classified. Most of it is believed to be for the deep oceans (the location of surveyed areas is also classi-

fied) and would be of enormous value to oceanographers. But the Navy argues that it needs the data kept secret as it uses it to determine the best sites for sensors to detect enemy submarines and to map the gravity anomalies which affect the flight of ballistic missiles. Occasional glimpses of part of the Navy data have been given on a "need to know" basis, producing, for example, the map of the North Atlantic sea mounts published by David Epp and Christian Smoot (see *Nature* 337, 254; 1989). But even in this case the location of the sea mounts was not given with full accuracy.

The Navy's tough policy on bathymetric data has done little good to US industry. General Instrument Corporation, the major US maker of multibeam sonar, has had to refuse several export orders, while Finnish, German and Norwegian companies have sailed away with business. The damage to US industry, plus the knowledge that it was becoming possible to buy foreign sonars that would map the sea floor as accurately and faster than NOAA's equipment, may have helped to prod the Navy into a more open attitude.

Most oceanographers attribute the change in policy to last year's appointment of Rear Admiral Richard Pittenger as Oceanographer of the Navy. Despite his background in anti-submarine warfare, he is believed to value academic research. But the Navy keeps quiet about its policy decisions and will not give reasons for its change in course.

### RADIOTELESCOPE

## Green Bank failure identified

### Washington

THE cause of the sudden collapse of the 300-foot radiotelescope at Green Bank, West Virginia, last November (see *Nature* 296, 336; 1988), on a night without wind, rain or snow, has been traced to the fracture of a single, highly stressed steel connection plate, according to an independent inquiry which submitted its findings to the National Science Foundation last week.

That conclusion leaves the National Radio Astronomy Observatory free to clear away the enormous tangle of steel that had been left undisturbed while the inquiry was in progress. But it makes it no easier to sort out the scientific and political issues surrounding the question of whether the telescope should be rebuilt.

The three-man inquiry panel found no evidence of inadequate maintenance of the connection plate, or of improper operation of the telescope. But modern computer structural stress analyses, show that stresses in many parts of the

telescope "were substantially higher than is permissible today".

The telescope's design problems can be overcome using modern techniques, says the report, and provide no technical obstacles to its replacement. West Virginia's two Democrat Senators, Robert C. Byrd and John D. Rockefeller, are already demanding that a similar, state-of-the-art telescope be built as the "best promise for jobs, education, tourism and scientific prestige" in a state with little else to offer in the way of large, basic research facilities. Byrd, who holds a powerful position in the Senate Appropriations Committee, says he "will aggressively pursue funding" for the telescope. Plans for a supplemental appropriation to the NSF budget for a new telescope are already under way.

But astronomers are not necessarily sure that replacing Green Bank would be the best use of the \$75 million required. The large telescope was valuable for survey and mapping and was able to detect

## Protest as Pasteur speaks English

### Paris

A DECISION to give the Pasteur Institute's journal an English title has caused confusion and protest in the French press, but seems to have left the scientific community unscathed. Under the banner "Goodbye Pasteur!", the French national newspaper, *Le Monde*, broke the news that, in future, the *Annales de l'Institut Pasteur* will be published only in English, for the first time since it was created in 1887. This, ran the article, sounds the death-knell for French-language science.

Two changes have been made to the journal. The title will now be *Research in ...* (immunology, virology or microbiology, according to the discipline covered). Second, the review panel has been widened to include non-Pastorians and foreign scientists. But, says the Pasteur Institute, articles submitted in French and accepted for publication will be printed in French, while articles in English will continue to have a French abstract. For the press, the changes signal the disappearance of a flagship of French science under the 'tyranny' of the English language. But the Pasteur Institute sees things differently. "In 1973 only 10 to 15 per cent of the articles we received were in English, but in 1987 the proportion was almost 100 per cent", says a spokeswoman. "But of the articles we published, 58 per cent were from French-speaking authors and over 80 per cent of these were originally written in English. The title of the review, however, suggested that it was not open to the scientific community as a whole and so researchers started to send their papers elsewhere. The *Annales de l'Institut Pasteur* has to survive."

**Peter Coles**

faint sources, including a pulsar in the Crab nebula. But according to Kurt Riegel of NSF's Division of Astronomy, a decision to rebuild the telescope would face competition from projects to upgrade the radiotelescope at Arecibo, to build large optical telescopes and to enhance the image-processing capabilities of the National Radio Astronomy Observatory's very large arrays.

If a new radiotelescope is not built, "it does not bode well for the site at Green Bank", according to the facility's director, Paul A. Vanden Bout. A 140-foot radiotelescope remains at Green Bank but it is 26 years old. A possible solution, already suggested by NSF officials, is to build the eastern end of the proposed Laser Interferometer Gravitational Wave Observatory (LIGO) at Green Bank. The project requires a facility in California and in the east to be run in coincidence. But Byrd and Rockefeller say that while they welcome LIGO, they want the radiotelescope replaced too.

**Alun Anderson**

## CANCER THERAPY

## Cancer data are puzzling

### Washington

THE US General Accounting Office (GAO) has uncovered a conundrum in breast-cancer therapy. Although there is good evidence from randomized clinical trials that chemotherapy following surgery is beneficial for premenopausal women with breast cancer that has spread to the lymph nodes, increased use of chemotherapy has not been followed by decreased mortality statistics. In 1987, Congress asked GAO — its investigative agency — to determine whether cancer patients were actually receiving the latest therapies being developed with federal money by the National Cancer Institute. In its latest report\*, GAO used data from the Surveillance, Epidemiology and End Results (SEER) programme to track mortality from breast cancer from 1975, when chemotherapy was first shown to be an effective treatment, until 1983, the latest year for which complete data are available.

Although there is still some debate over the value of chemotherapy for breast-cancer patients whose cancer has not spread to the lymph nodes, clinical trials have shown that for node-positive premenopausal women, chemotherapy is beneficial. Nevertheless, despite an increase in the number of women receiving chemotherapy between 1975 and 1983, there is no detectable change in survival figures. The analysis confirmed that age and race are significantly related to the probability of dying from breast cancer.

GAO proposes three explanations for its results. The first, and least likely, is that chemotherapy is not so beneficial despite studies to the contrary. A second possibility is that doctors are not giving appropriate or sufficient drugs to their patients, and a third possibility is that the improvement that can be expected from chemotherapy is not great enough to be detected by GAO's statistical techniques.

But Vincent DeVita, Physician-in-Chief at Memorial Sloan-Kettering Cancer Center and former director of the National Cancer Institute, says GAO is premature in raising the long-term survival issue. He argues that only a small fraction of the appropriate patient population was receiving chemotherapy in 1975, and newer therapies will yield a more encouraging picture in a few years. DeVita accuses GAO of designing its study to validate preconceived ideas.

The GAO report calls on the Department of Health and Human Services to conduct a larger study to explain the curious findings.

## RESEARCH ANIMALS

## Activists infiltrate Stanford

### Berkeley

THE Stanford University biology faculty has become involved in a new controversy over the use of animals in research by criticizing an undergraduate course taught by two animal rights activists. A letter from the biology faculty objecting to the course was obtained by the two instructors, who are now demanding an apology.

Stanford has had difficult relations with animal rights activists for the past several years. Protesters have caused more than a year of costly delays for Stanford in building both a new animal facility and a new biology research building (see *Nature* 329, 477; 1987). So the biology faculty was dismayed to learn last autumn of a Stanford course called "The Case for Animal Rights", being taught by Kimberly Sturla

and Lise Giraud of the Peninsula Humane Society, both of whom have been involved in the building protests.

The course was part of a popular programme called Stanford Workshops on Political and Social Issues (SWOPSI), intended to expose students to controversial subjects. Biology chairman Philip Hanawalt says department members did not object to a course on animal rights, but were concerned because one of them who had attended the class reported that the instructors showed ignorance of the scientific arguments for using animals, and created a hostile environment for speakers invited to present that view. The faculty voted unanimously that a letter of objection should be sent to the dean of undergraduate studies.

"We decided that it is the prerogative and duty of the academic faculty to maintain quality control in what is taught to Stanford students", said Hanawalt, "and therefore it was entirely appropriate for us to make comments on this." Those who observed the class and wrote the letter have requested anonymity out of fear of reprisals by the activists.

The letter, which was addressed to

Thomas Wasow, dean of undergraduate studies, with a copy to Margo Horn, director of SWOPSI, questioned the qualifications and scientific knowledge of the instructors, and accused them of requiring ideological compliance of the students and of failing to present both sides of the issue. When the instructors heard of the letter and asked for a copy, Horn consulted Wasow, who agreed that she could send them one. Wasow says that at the time he did not consider the letter, which bore the names of the entire biology faculty, to be confidential. Hanawalt says such internal memoranda should be considered confidential. He compares its release to the instructors to the release to a faculty member denied tenure the letters upon which that decision was based.

Through their attorney, Sturla and Giraud have publicized the letter, called it "defamatory" and demanded an apology. Sturla claims she is "very qualified", to teach the course, and points out that the course dealt with issues other than research, such as the use of animals for food and in rodeos. She adds that in each case, experts were brought in to present each side of the argument.

David Maurice, a professor of ophthalmology who spoke in favour of animal use in research, says he was given a polite hearing, but felt that his words fell on deaf ears, as the students had already been strongly biased against animal use. Maurice, who himself co-taught a seminar on alternatives to animal use several years ago, questions whether activists like Sturla and Giraud are the right people to teach such a class.

**Marcia Barinaga**

## SCIENCE POLICY

## Brazilian appointment

### São Paulo

CONTINUING its quick-change approach to science and technology policy, the Brazilian government last week selected a secretary for its new Special Secretariat for Science and Technology, a cabinet-level body created just two months after the sudden extinction of the Ministry for Science and Technology. The appointment of Décio Leal de Zagottis, director of the influential Polytechnic School of the University of São Paulo, may signal a change in computer-industry policy. In the two months following the death of the old ministry, science policy and the management of several government institutes went to the Industry and Trade Ministry, whose minister, Roberto Cardoso Alves, opposes Brazil's protectionist stance towards the computer industry. The new secretary says he will oppose change.

Ricardo Bonalume Neto

## Proposal divides biologists

### London

BRITAIN'S biology community is divided on the merits of the new plan to restructure biology teaching and research in universities (see *Nature* 338,363; 30 March 1989). Some are resigned to the plan, others will strive to persuade the Universities Funding Council (UFC) to modify some of the proposals.

The report, distributed to universities

last week, was carried out for the University Grants Committee (which was dissolved last week) by a group led by Professor Sir Richard Southwood of the University of Oxford. It was the subject of heated discussion at the first meeting on 31 March of a new group comprising more than 50 heads of biology departments.

The most controversial aspect of the plan is the proposal to group existing

departments into two kinds of much larger departments, one focusing on molecular biology and the other on more traditional areas such as ecology and evolutionary studies. This was criticized as "disastrous", "illogical" and "an odd reversal of the current trend towards integrative biology". One speaker said it would divorce the techniques of molecular biology from the subject areas in which they were being applied. The department heads agreed that a rigid division between the two types of department would be detrimental.

On the other hand, they disagreed over interpretation of the report, some saying it was too dogmatic and others insisting that there would be flexibility.

The proposal to group all biology departments in a university into a single school of biological sciences was also welcomed. Most agreed that fragmentation is undesirable, but the report was criticized for putting forward only one model for integration. The group agreed that for different universities, different strategies would be necessary.

The group also agreed with the recommendation that pre-clinical teaching of biology in schools of medicine, dentistry and veterinary science should be the responsibility of the new schools of biological sciences. Professor James Callow, of the University of Birmingham, described this as the "most radical proposal" in the plan, but the review committee was criticized for not studying this problem in more detail. This proposal is likely to meet fierce opposition in medical schools.

The biology heads were particularly concerned about the effects on biology of the planned restructuring of other sciences. Although the biology plan recommends no closures, the expected closure of more than ten university chemistry departments is expected to have a knock-on effect on biology.

There was also concern about the future quality of entrants into university biology courses. Changes in the content of school examinations are likely to mean that students have less factual knowledge in the sciences. The biology heads also fear that the courses provided at British universities may compare badly with more comprehensive and longer courses at other European universities. One proposed solution to both these problems was that England should follow Scotland in introducing 4-year degree courses, instead of the present 3-year courses.

The committee elected by the new group of heads will put a response to the biology report formally to the new Universities Funding Council later this month. This report was intended to be only the precursor to a more wide-ranging review, but was carried out quickly so that restructuring of biology would not lag too far behind restructuring in the other sciences.

**Christine McGourty**

### SOVIET SPACE

## Phobos failure raises doubts

### London

THE failure last week of Phobos-2, the second of the two Soviet Mars probes launched last July, could hardly have been worse timed for Soviet space planners. During the past few months, there has been growing public criticism in the Soviet Union of the cost of space, particularly of deep-space missions with no obvious economic spin-off. One of the chief advocates of swingeing cuts in the space budget is Mr Boris Yeltsin, who on 26 March won a resounding election victory over the 'official' candidate. The following day, contact with Phobos-2 was lost.

The two-craft Phobos mission included a wide range of investigations of Mars and its satellite Phobos, including the firing of a laser at Phobos and the landing of a 'hopping' probe to investigate the satellite's surface. It carried experiments from 13 countries and multinational agencies and had been presented as a first step to an international manned mission to Mars early in the next century. But Soviet media coverage of the mission has from the beginning been tentative.

The original mission consisted of two spacecraft, carrying different experiments. Early in September, Phobos-1 came to grief when a ground-based computer error led to its being sent an incorrect command. In December, the main transmitter on Phobos-2 failed, but the craft arrived on schedule and on 23 January was inserted into an orbit around Mars. It functioned as planned for the next nine weeks, returning several photographs of the surface of Mars and Phobos.

On 27 March, the command to rotate the probe to prepare for the close (50-m) transit of Phobos was apparently followed correctly — but mission control found it impossible to re-establish contact. Two days later, the head of the Glavkosmos space agency said his experts were working round the clock to try to restore the links. But these efforts proved fruitless.

Although Soviet newspapers have made the best of the photographs and data already received from Phobos-2, these are unlikely to restore public confidence. But

as *Pravda* revealed last week, there is equal resentment that it will be a Japanese journalist (paying his fare in hard currency) and not a Soviet citizen who will be the first media representative to visit the Mir station (see this page).

**Vera Rich**

### JAPAN IN SPACE

## Journalist plans scoop

### Tokyo

THANKS to the Soviet Union, the first Japanese citizen to journey into space may be a journalist from a private television network rather than one of the astronauts training for a ride on the US space shuttle.

Last week, the Tokyo Broadcasting System (TBS) network signed an agreement with the Soviet Commission for Space Exploration (Glavkosmos) that will allow a TBS reporter to spend six days aboard the Mir space station in 1991. The reporter will make live broadcasts to Japan every day throughout his stay in the station.

The agreement comes as a shock to Japan's National Space Development Agency (NASDA), which has been planning for years to put the first Japanese astronaut in space aboard the US space shuttle. Although a final date for the reporter's space voyage has yet to be set, TBS has arranged the flight to commemorate the network's 40th anniversary on 10 May 1991. There is thus a strong possibility that TBS will 'scoop' NASDA's plans to put an astronaut on the space shuttle in July of the same year.

Soviet journalists are also upset about the agreement. *Pravda*, the Communist party daily newspaper, welcomed the Soviet authorities' decision to offer a journalist a space flight but complained that only foreigners could afford to pay the fare. The Communist Party youth newspaper *Komsomolskaya Pravda* carried, under the headline "Prestige trampled underfoot", pictures of Yuri Gagarin, the first man in space, Valentina Tereshkova, the first woman in space, and a Japanese 10,000-yen banknote with the caption "The first journalist in space?".

## OIL SPILL

# Shipwreck fouls the water

✓ **Berkeley**

THE largest oil-tanker spill in US history has turned Alaska's Prince William Sound from a pristine environment into a disaster area. Biologists are not yet able to assess the full extent of the damage to the area's wildlife, but the political damage to those pressing for further oil development in Alaska is already plain.

On 24 March, the fully-loaded oil tanker *Exxon Valdez* struck a reef shortly after leaving the Alaskan pipeline terminal in Valdez, southern Alaska, spilling 10 million gallons of crude oil. The tanker's captain, who had been drinking before the accident, had left the ship in the hands of a crewman not certified to pilot the ship within the sound.

Little oil from the spill was recovered, and angry fishermen and environmentalists blame Exxon and the Alyeska Pipeline Service Company, which manages the pipeline, for a disorganized clean-up effort that squandered precious time. Floating booms intended to be deployed quickly to contain a spill did not reach the site until more than 10 hours after the wreck, said Jon Lyman, of the Alaska Department of Fish and Game. Alyeska officials blamed the delay on the fact that the barge intended to carry the booms was unloaded for repairs.

Alyeska spokeswoman Beverly Michaels said that skimmers and booms are not practical for such a large spill, and Alyeska was prepared on the day after the spill to apply chemicals that disperse the oil into the water. But fishermen, concerned about the toxic effects of the dispersants and dissolved oil, persuaded the Coast Guard to delay permission to use them. By the time permission was received the following day, said Michaels, high winds made it impossible to apply the dispersant from aircraft. Debate still continues over whether dispersants or containment and collection would have been best, but after two days of heavy winds the oil was spread over 550 square miles, ruling out either method. Fishermen and state officials joined Exxon and Alyeska in using barriers to protect the most environmentally sensitive areas.

Because the Valdez spill is in a relatively enclosed area, it formed a continuous blanket over the water, potentially trapping aromatic hydrocarbons, such as benzene or toluene, in the water beneath the oil. Jacqueline Michel, an environmental chemist for the National Oceanic and Atmospheric Administration (NOAA), said laboratory studies have shown such chemicals to be highly toxic to planktonic fauna.

The herring-roe fishery will be the first influenced by the spill. Within the next few weeks, the fishery would normally

begin to capture herring that have entered the sound to spawn, and allow them to deposit their eggs on kelp, which is harvested after the fish are released. Sale of this year's harvest may be banned if hydrocarbon contamination is detected in the spawning areas or in the roe that is collected.

High priority was given to protecting the economically important hatcheries where young salmon are raised and returned to the sea in May. Some are tagged each year before release, and survival data are collected when the adults are caught by fishermen several years later. Tags from those released this year will provide information on the impact of the spill on the salmon population.

Lyman said that birds and sea otters are particularly vulnerable to oil spills, because the oil destroys the insulating qualities of their fur and feathers. Exxon brought in an animal rescue team from California, but rescue attempts were hindered by the inaccessibility of the rocky beaches in the area. Tens of thousands of birds and otters live in the sound, and many of those are likely to have been harmed or killed by the oil, but a week after the spill only a handful had been rescued and cleaned. The cleaned animals will be tagged before their release, to aid biologists in determining the fate of animals following the spill.

Migratory puffins, terns, cormorants and other birds are just beginning to enter the area. Their nesting grounds, as well as the areas where sea lions will give birth in May, were included among areas to be protected with booms from the progressing oil slick.

Exxon will hire local residents to clean oil from hundreds of miles of shoreline. Exxon spokesman Brian Dunphy said absorbent pads will be used to soak up the oil, and high-pressure hoses will blast it off rocks. Michel, of NOAA, said wave action and biological activity will purge the oil from exposed sites, but sheltered areas may remain contaminated for years.

Barges and tugs head to clean up the worst of the oil spill in Alaska's Prince William sound, where the *Exxon Valdez* ran aground spilling 270,000 barrels of crude oil.

## NUCLEAR SAFETY

## Cuba signs agreement with Soviet Union

London

CUBA has signed a nuclear safety agreement with the Soviet Union, regulating Soviet assistance at the Cienfuegos nuclear plant and "other nuclear projects" under construction. The Soviet side is to equip Cuban nuclear safety laboratories with services, hardware and documentation, and will also arrange consultancy services on how to organize radiation monitoring. Cubans will be trained in the Soviet Union as operators of nuclear power stations.

Vera Rich

The spill is likely to cause political fallout, as the battle continues in Congress over oil development in the Arctic National Wildlife Refuge, adjacent to the Prudhoe Bay area which now supplies oil to the Alaskan pipeline. Environmental groups have opposed the development (see *Nature* 327, 9; 1987), while oil companies and the Bush administration have argued that development is essential, and can be conducted in an "environmentally sensitive" manner. The Valdez spill did not change administration policy, but environmental groups expect its effects on public opinion to be felt in Congress, where competing bills are being considered that would either open the area for development or declare it a wilderness area, thus preventing oil drilling. Opponents of oil development off the California coast expect the spill to aid their cause as well.

Although an oil spill at the pipeline terminal is not the same as the general environmental disruption feared from construction of oil exploration sites in the Alaskan wildlife refuge, Don Hellmann, of the Wilderness Society, said it raises the question of whether assurances from oil companies can be trusted. "The oil companies have been saying all along that they can drill without harming the environment, and if there is a problem such as a spill, they can take care of it right away. Now we've seen that they're wrong on both counts."

**Marcia Barinaga**

Associated Press

## Operators to cooperate

### Boston

NEXT month in Moscow, the World Association of Nuclear Operators (WANO) will begin formal operations, ushering in what supporters hope will be an era of increased international cooperation among the world's nuclear power industries.

WANO was conceived initially in response to the accident at the Chernobyl reactor in 1987. Participating power plants will share information about the safe operation of their plants and the details of any "off-normal" events through a worldwide computer network. The association has already opened regional centres in Paris, Tokyo and Atlanta (Georgia), and a coordinating office in London. A fourth is due to open in Moscow later this month. In a remarkable show of solidarity, the organization will include the participation of every nuclear utility in all of the 31 countries that use the technology to generate electricity.

Through its regional centres, the group will collect data about all mishaps and untoward events at nuclear power plants, and will organize workshops and technical exchange visits between nuclear operators from different nations.

While other international organizations exist to promote the safe use of atomic energy, WANO is unique in its exclusive orientation to industry, and its goal of uniting nuclear-plant operators worldwide. WANO is modelled on an existing organization in the United States called the Institute of Nuclear Power Operations (INPO) which was also formed in response to a nuclear mishap—the partial meltdown at Three Mile Island in 1979 (see *Nature* 338,190;1989).

Greater information exchange among nuclear operators might have prevented the operator error that led to the accident at Three Mile Island, according to many INPO staff. Addressing participants at an INPO conference in Atlanta last fall, Lord Marshall, chairman of the WANO Steering Committee, stated that the accident at the Chernobyl reactor "never would have happened" if WANO had been in place and "working effectively". "Peer group pressure" would have forced changes in the "unacceptable" degree of reliance on the operator in the safety design of the Chernobyl plant, said Thomas Eckered, acting director of the London WANO coordinating centre.

Marshall stressed the importance of the choice of Moscow as the location of the inaugural meeting of the group. That, he said, shows the acceptance by the world nuclear industry of Soviet commitment "to *glasnost* and *perestroika* in their nuclear business."

**Seth Shulman**

## Proliferation of nuclear subs

### Boston & São Paulo

FEARS that the acquisition of nuclear-powered submarines by Brazil, India and Canada will blur the line laid out in the Nuclear Non-Proliferation Treaty and foster the spread of nuclear weapons to developing nations are largely unfounded, according to the majority view at a meeting held last week at the Massachusetts Institute of Technology (MIT). But military and technical experts from several nations, including those planning to acquire nuclear-powered submarines, agreed that there are real fears that deployment of nuclear submarines could trigger regional arms races in South Asia and South America.

Brazil, India and Canada are all planning to build or buy nuclear-powered submarines. India last year leased a nuclear submarine from the Soviet Union and is rumoured to be negotiating for three more, even as it continues work on its own development programme. K.K. Nayyar, retired vice-admiral of the Indian Navy, defended his nation's nuclear-submarine programme not only by emphasizing its deterrent capability but also by acknowledging India's desire for a stepped-up military presence in the Indian Ocean. "India represents 17 per cent of the population of the planet", Nayyar stated, "we want to be there to be reckoned with".

Brazil too has regional power plans. A statement from Mario Cesar Flores, an admiral in the Brazilian Navy, said that

Brazil's ambition to have a "strong presence" in the South Atlantic leads it "in a firm, prudent and deliberate fashion, to the nuclear-powered submarine". Brazil was apparently impressed by the performance of British nuclear submarines during the Falklands war.

Three conventional submarines are now being built in Brazil with West German help while indigenous efforts are made to develop small reactors and enrich nuclear fuel at the Centro Experimental Aramar at Iperó near São Paulo. According to Adrian English, a US expert on Latin America's military balance, as soon as Brazil deploys a nuclear-powered submarine, "two to four nations in the region will be sure to follow suit", including Argentina, Chile and Cuba.

The role of nuclear-powered submarines in regional conflicts seems a bigger problem than their impact on nuclear-arms programmes. Several participants at the meeting pointed out that the countries currently investigating the development of nuclear submarines already have nuclear-power programmes and "plenty" of plutonium for weapons at their disposal. Brazil's Admiral Othon Pihheiro, known locally as the "Brazilian Rickover", claimed success for the nuclear enrichment programme last week, saying that the first batch of enriched uranium reactor fuel will be delivered at the end of the year.

### ENVIRONMENTAL PROTECTION

## Trouble at the mill in Australia

### Sydney

PLANS for a \$1,000-million chemical pulp mill in Tasmania have been scrapped after the Australian government decided to impose strict environmental controls as a condition of approval for foreign investment in the project. The mill, at Wesley Vale, was to have been a joint venture between the Australian company North Broken Hill Peko and its Canadian partner Noranda.

Such environmental guidelines are usually set by the state government. It is believed that the Tasmanian government agreed to loosen its guidelines because of the employment opportunities offered by the project. But in this case, because of the level of foreign investment, the project had to be approved by the federal government's foreign review board.

At issue is the production of dioxins, which occurs when mills bleach paper with chlorine. In humans, dioxin exposure causes the skin disorder chloracne and has been linked to other illnesses. According to government sources, the companies involved in Wesley Vale were not prepared

to spend enough money to replace dioxins in the bleaching process, or to change the mill's effluent pipeline into Bass Strait.

The Minister for the Environment, Senator Graham Richardson, has come under strong pressure from the government to develop clear-cut environmental guidelines. While agreeing to do so, Richardson has stated that differing circumstances in individual cases may make them difficult to formulate.

Companies at present planning three other pulp mills in Victoria, New South Wales and West Australia, all similar in scale to Wesley Vale, are unlikely to proceed without comprehensive guidelines.

Prime Minister Bob Hawke told the Australian Broadcasting Corporation radio programme "PM" that he recognized that the loss of the mill would damage both investment in Australia and export earnings. "As long as I'm Prime Minister I won't have development at any price. Each day they would be dumping 13 tonnes of organochlorides into the ocean and I will not allow it."

# Coming of age in anthropology?

Adam Kuper

With the screening in several countries of a film on the subject, the controversy over Margaret Mead's work in Samoa rumbles on. Underneath the thunder and lightning, considerable anthropological issues are at stake.

*MARGARET Mead and Samoa*, a new Australian film made for television, is the latest engagement in a controversy which began in 1983 with the publication of Derek Freeman's book, *Margaret Mead and Samoa: The Making and Unmaking of an Anthropological Myth* (Harvard University Press). The film has been shown in Australia, the United States, Denmark and Sweden; it is presented not just as a journalistic review, but as a contribution to the debate in its own right, a claim which Derek Freeman endorses in person. Indeed the promise is that matters will be settled once and for all — the film opens with the dramatic announcement that the issues in contention "will be resolved by startling new evidence presented in this programme".

But what is all the fuss about? Why did a critical book on Samoan ethnography stir up such excitement? The public has been led to believe that if Mead is shown to be wrong about adolescent girls in Samoa, this will have decisive implications for debates about how far our capacities and characters are shaped by experience, especially childhood experience, and how far they are fixed by heredity. These are some of the greatest issues which have exercised social scientists in the twentieth century. In the manner of the cinematic genre, however, let us backtrack and recall the story so far...

Mead's study of Samoan adolescent girls was carried out in 1925, when she was 23 years old. It was reported over 60 years ago in *Coming of Age in Samoa* (William Morrow, 1928), a short book written in popular style. At her publisher's suggestion, Mead added a final chapter which drew a moral from Samoa for educationists in the United States, and her book became a hugely and enduringly successful best-seller. She also wrote a sober ethnography of Samoa, *Social Organization of Manu'a*, which was published by the Bishop Museum in Hawaii, and together with various collaborators she later carried out more sophisticated studies of other Pacific communities.

Nevertheless it is this famous apprentice book which Freeman chose to try and refute more than half a century later, identifying it as the cornerstone of relativist, anti-biological social science.

Mead spent nine months in Samoa, but her main study of 50 girls in one village was carried out in a period of four months,

whether adolescence was necessarily a period of stress and discord, caused by the ineluctable biological processes of puberty, or whether the problems that American adults experienced with teenagers could be put down to specific cultural factors, and so, perhaps, ameliorated or even eliminated by making changes in schools or in family life. According to Mead, adolescent girls in Samoa had no problems of sexual adjustment, enjoying a fulfilling and undemanding love life. They seemed to have an untroubled passage to maturity. There were few sulky, angry adolescent rebels. Adult Samoans were also relaxed, tolerant and genial. Emotions seldom ran high and there were no intense attachments, even within the immediate family. The society was remarkably free of violence and aggression. The conclusion was that the storm and stress of American adolescence was a culturally specific phenomenon, and had to do with American attitudes to sex and to competition, and to the intense pressures of family life.

Freeman disagrees with most of Mead's ethnographic generalizations. He says, for example, that there is strong mother-child bonding in Samoa, that parental discipline is severe, and that there is a high level of general aggression and violence. Adolescent girls do not enjoy sexual freedom; the Samoans put a premium on virginity, but rape is common, and because of the emphasis on chastity a girl may actually be forced to marry her assailant.

The research for Freeman's critique of *Coming of Age in Samoa* was begun in the 1940s, and his own book was substantially completed by the 1960s. Unfortunately it appeared only some two decades later, several years after Mead's death. But although we are denied Mead's response, a number of regional specialists have assessed Freeman's book in some detail.

Did he successfully refute Mead's conclusions? The consensus among anthropologists is that both Mead and Freeman over-generalized in characterizing the 'ethos' of Samoan culture; in any case,

Duped? Margaret Mead in 1958.

a very short time by modern fieldwork standards (and her work was badly disrupted by a hurricane). Yet her research was not without merit, despite some obvious shortcomings. She became a confidante of the village girls, and carefully recorded their activities and conversations; she applied various psychological tests; and she systematically collected biographical information.

The main lines of Mead's Samoan study are familiar to generations of readers, including millions of college students in the United States. The central issue was

Cornell Capa

defining national character is a hopelessly subjective and impressionistic project, which most contemporary anthropologists have abandoned. The experience of adolescence in Samoa is a different matter, however, and it should be possible to collect accurate information on such questions as the punishment of children, sexual crime, courtship procedures and other matters on which there has been fundamental disagreement. Yet on issues of this kind, Freeman's own data are by no means uncontroversial. For example, he and his wife carried out a 'virgin census', which established the sexual purity of Samoan adolescents. He does not explain how this was done in a community famous, on his own testimony, for its teasing of investigators.

Freeman is also often uncritical in his use of sources. His statistics on criminal violence in Samoa, for instance, are derived from a mixture of reports from different periods and of diverse provenance. He uses them to construct 'rates' and then makes unsystematic comparisons with juvenile delinquency in American and British cities. (Oddly enough, his main comparative source on youth delinquency is an old study by the notorious fraud Cyril Burt.)

What, then, does the film add to the controversy? The central figure is Freeman himself. He is shown in his garden in Canberra, padding through the woods in gloves, driving what seems to be an armoured personnel carrier through quiet suburban streets, wearing funny woollen hats, dressed as a Samoan and as a naval officer — all the while pressing his charges against Mead and her defenders.

### Leg-pulling

The main thrust of the film is an endorsement of Freeman's account of how Mead went wrong. Freeman has always claimed that Mead was systematically misled by her Samoan informants. In the film a young American anthropologist testifies that Samoans do go in a great deal for leg-pulling. An elderly Samoan chief then reiterates the point that Samoan girls are notorious teasers. Finally, an 80-year-old Samoan lady appears on the screen. She is identified as one of Margaret Mead's informants from 1925, and a voice-over tells us that "her account will settle once and for all the controversy. . ." — yes, she says, yes we lied to her, "we just lied and lied".

Epimenides the Cretan who said that all Cretans are liars posed a famous problem for logicians. Samoans who say that all Samoans are liars discredit those who believe anything they may say. Surely Professor Freeman cannot believe that the testimony of a confessed liar will finally persuade his colleagues that Mead's account of Samoa was wrong?

What of the wider issues? Probably, the

general view among anthropologists is that we are very plastic creatures, and that there is considerable culturally induced variation in personality, values and life strategies. But this 'relativist' orthodoxy has always had to contend with a countervailing search for a bed-rock of 'human nature', even of 'nature', that is shared by all human beings, perhaps all primates. Freeman hopes to establish general propositions about human nature; but he is cagey about whether he expects these to be of the sort proposed by Konrad Lorenz, by E.O. Wilson or even by Sigmund Freud.

Yet, although the battle-lines are clearly drawn, certainly by Freeman and by the media, the debate seems in a curious way to pass them by. Even if Freeman's observations are accurate, and Mead's are mistaken, this would not greatly affect our contemporary view of the adolescent experience. Freeman has not tried to show that ethology or social biology offer a more powerful theory of adolescence than any other on offer. He himself quotes the conclusion of H. Katchadourian (*The Biology of Adolescence*; W.H. Freeman, 1977) that "research on ordinary adolescents has generally failed to substantiate claims of the inevitability and universality of adolescent stress", a judgement which would have discomfited neither Mead nor her supervisor, Franz Boas, half a century ago.

Freeman's alternative claim — which he makes in the name of Karl Popper — is that he has refuted Mead. By disconfirming her Samoan findings, he has kicked away the essential crutch of her cultural relativism. This is to assume that Mead's study of Samoan adolescents, carried out 60 or so years ago, was and remains the crucial experiment for the cultural relativists. The claim has only to be formulated in this straightforward way for its flaws to be apparent.

There is therefore little in the view (fostered by Freeman, and taken for granted in this film) that the Freeman-Mead debate is a crucial round in the battle between cultural relativism and a biologically grounded, scientific, universal view of man. Nor are there serious grounds for the claim, supported by some conservatives, that Freeman has undermined the basis for liberal educational philosophies. Nevertheless, the debate *has* had a special resonance within anthropology, for it has fed the contemporary unease about ethnographic fieldwork and writing.

Doubts on this score trouble anthropologists more than any substantive questions today, for they have invested a great deal in the credibility of their characteristic research methods. It is often said that ethnographic fieldwork is to anthropology what the blood of the martyrs is to

the Church. Many leading anthropologists prefer to call themselves ethnographers, and practically every move an anthropologist makes gains in respectability if it is called 'ethnography'. One goes into the field 'to do ethnography' and comes home 'to write an ethnography', and most professionals firmly believe that the better ethnographies will always be of more enduring value than even the most ingenious anthropological theorizing.

### Participant observation

A revolutionary new way in which to do ethnography, participant observation, was introduced shortly before Margaret Mead sailed to Samoa and quickly became the central procedure of modern anthropology. Earlier methods of data collection had been drawn from other sciences. For example, the first professional — scientific British ethnographic expedition, the Cambridge University Expedition to the Torres Strait, in 1898, was conducted by natural historians in the manner of a zoological field study. The natives were observed and their responses tested; and although they were certainly allowed to speak, this was only in answer to scientific interrogation. During the First World War, a Polish scientist at the London School of Economics, Bronislaw Malinowski, spent two years on a small island in Melanesia and invented the modern form of ethnographic field enquiry. Malinowski insisted that the observer had to understand the native language and appreciate the actor's point of view in order to assess what he was told, to grasp the difference between what people said and what they did. Customs made sense in context, actions had meaning, people guessed at each other's intentions and adjusted their own behaviour accordingly in order to achieve goals which might be hidden, contradictory, culturally specific and situationally variable. The observer had to come off the verandah (as he said, in what became a famous phrase), because distance lent only the illusion of objectivity, and prevented genuine understanding of what was going on.

Ethnographic fieldwork on the Malinowski model has become one of the main research strategies in the human sciences, and its insistence on the context of action has influenced the study of other primates too, notably by way of the functionalist field studies of African apes initiated by Irvén DeVore in the 1950s. But notwithstanding its successes, it is evident that the move from the neutral, precise and systematic methods of the Torres Strait Expedition to the personal, messy and home-made methods of a Malinowski has its costs.

If the observer must participate in order to learn, then appeals to the authority of personal experience and to unique insights become uncomfortably prominent.

Obviously, it is not going to be easy to control for observer bias. So how can the reader judge between competitive accounts of a particular culture? These methodological questions troubled many anthropologists who did not take the substantive issues in the Freeman-Mead controversy very seriously. Freeman claimed that he could refute Mead by opposing his observations to hers, but this has turned out to be a difficult task.

To begin with, there have been other attempts to test Mead's findings, which have reached less severe conclusions. Lowell Holmes, an anthropologist who went to Mead's Samoan village 30 years after her study, specifically in order to reassess her work, concluded that her report was substantially accurate (*Quest for the Real Samoa: The Mead/Freeman Controversy and Beyond*; Bergin and Garvey, 1987). In the film, Freeman tries to show that Holmes is biased in favour of Mead for personal reasons, but does not challenge Holmes's findings in a systematic way. Other psychologists and anthropologists who have done research in Samoa are divided in their judgements of her work. (For examples of the various views see "Speaking in the Name of the Real", *American Anthropologist*, Vol. 85, 1983, and Holmes's review of relevant studies in Chapters 8 and 9 of his *Quest for the Real Samoa*.)

But even if Freeman's ethnography is reliable, this does not necessarily demonstrate that Mead got it wrong. She worked in another part of Samoa (under a different colonial regime, with different missionary influences and with a different economic base), and she was working 20 years — and a world war — before Freeman began his own field studies. It may be that both reported what they saw quite accurately, but that they saw different things because things were really different. Alternatively, they may have accurately reported the divergent perceptions of two different segments of the Samoan population. It is perfectly possible that Samoans had two conflicting theories about adolescence, one put about by adults, the other an unofficial, underground ideology of the young people themselves. Freeman may be presenting the point of view of respectable elders, while Mead (who participated mainly in the lives of the adolescent girls) may be generalizing from what was an informal sub-culture.

According to a body of opinion within anthropology, uncertainties of this kind are inevitable and cannot be resolved. If action, even perception, is culturally conditioned, then this applies not only to the subject of study but to the anthropologist as well. No observation is neutral; no observer can free him or herself from the constraints imposed by culture, status and life history. If observers do agree, then

In the field: Derek Freeman in Samoa, 1946.

this is probably because they share a bias. In his book *Orientalism* (Pantheon, 1978), Edward Said has argued that 'Orientalists' constructed an Oriental world to suit the purposes of the Occident.

The Freeman-Mead controversy has therefore fed a 'reflexive' tendency in ethnographic enquiry. The observer should be conscious of the contingent nature of research, and the final text, the ethnography itself, should not mimic scientific presentations but should be experimental, multi-vocal, ironical. Attention should be paid to the circumstances which produced the classic ethnographies, and to the rhetorical tricks which are used to persuade the reader of the ethnographer's authority. (See *Writing Culture* edited by James Clifford and George E. Marcus; University of California Press, 1986. And George E. Marcus and Michael M. J. Fischer's *Anthropology as Culture Critique: An Experimental Moment in the Human Sciences*; University of Chicago Press, 1986.)

This movement drew inspiration from contemporary critical philosophies, particularly those of Foucault and Derrida, and came to constitute a 'post-modernist' school within anthropology, as in other social sciences. One relevant development was an ethnographic sociology of science, which began from Thomas Kuhn's proposition that scientific paradigms had many of the characteristics of ideologies. Scientists were studied as though they were exotic tribesmen. The intrepid explorers discovered that the practice of laboratory research bears little

relation to the methodological accounts which figure in the textbooks, and which preface reports of findings in scientific papers. The conclusion was that scientific discoveries are constructed and established by social processes; that scientific consensus is a function of academic politics. (See Steve Woolgar's *Science: The Very Idea*; Routledge, 1988. And Bruno Latour's *Science in Action*; Open University Press, 1987.)

Post-modernists in anthropology are acutely alert to the importance of disciplinary politics, which play such a part in their theories. Accordingly, they organized effectively within the United States, where the entrenched cultural relativism provided fertile ground for their doctrines. Elsewhere their influence has been patchy at best. Even within American anthropology there has been a spirited and increasingly powerful counter-reaction. (See P. Steven Sangren, "Rhetoric and the Authority of Ethnography" *Current Anthropology* 29:3, 405-435; 1988.)

Yet even if it has only a brief vogue, the post-modernist challenge has already had a significant impact. Those who are formulating a response would not, on the whole, propose to reinstate the fiction of an objective observer who can bear witness to another culture 'as it really is'. Nor do they deny that research is a social process, and that ethnographies are social constructs. But this does not mean that there can be no firm standards. There is a discipline inherent in the process of ethnographic discovery. The observer and the subject do not simply circle round each other in mutual incomprehension — rather, they engage in a dialogue in which tentative agreement may be reached about actions and their meanings.

The ethnography which results is not a work of art, to be read more or less perceptively. It is a contribution to a debate about specific social processes and their significance. An ethnography will be taken up by a community of experts (including natives) who can call upon their experience of life in particular societies, and who will refer to a body of published observations and interpretations written from different perspectives and within a variety of disciplinary traditions. There is, then, an authority in ethnography, one which is not necessarily embodied in any one account, but which is emergent in the processes of expert research, comparison, evaluation and debate. Derek Freeman's crusading style does a disservice to rational academic discourse, but his dogged polemics have at least made many people aware that there are considerable issues at stake in contemporary anthropological research. □

Adam Kuper is Professor in the Department of Human Sciences, Brunel University, Uxbridge, Middlesex UB8 3PH, UK, and editor of *Current Anthropology*.

# Heliocentric tangents

SIR—The heliocentric hypothesis, so ably championed by Copernicus and Galileo<sup>1</sup>, is authoritatively said to have originated with Aristarchus of Samos in the third century BC. *Sand-Reckoner*, written by Aristarchus's younger contemporary Archimedes before 216 BC<sup>2</sup>, attributed to Aristarchus a book containing the hypotheses "that the fixed stars and the sun remain unmoved, [and] that the earth revolves about the sun in the circumference of a circle, the sun lying in the middle of the orbit . . .". Aristarchus's (lost) book is thought to have "clearly . . . also included some kind of geometrical proof"<sup>3</sup>.

Aristarchus had also produced a treatise *On the sizes and distances of the Sun and Moon*, which has survived intact. Its "excellent" methodology confirms that Aristarchus's (probably later) heliocentric hypothesis was similarly "not irresponsible" but rather the work of a "conscientious astronomer"<sup>4</sup>.

Nicholas Copernicus's *De Revolutionibus* (1543) acknowledged Aristarchus but not his heliocentric hypothesis<sup>5</sup>; however, it seems certain that Copernicus was also acquainted with the latter. For example, his original manuscript had referred to the opinion of Aristarchus on the movement of the Earth, but this reference was subsequently "suppressed"<sup>6</sup> or "scored out"<sup>7</sup>. Moreover, in relating the views of Philolaus, Heraclides and Ecphantus on the question of movement of the Earth, Copernicus's Preface quoted from *De Placitis Philosophorum* of pseudo-Plutarch, a work in which may also be found: "Aristarchus places the Sun among the fixed stars, and holds that the Earth moves around the Sun's circle"<sup>8</sup>. And *De Revolutionibus* (IV, 32) cites Archimedes' *Measurement of the Circle*, a treatise commonly found in the company of *Sand-Reckoner*<sup>9</sup>.

Copernicus's unquestionably pivotal contribution to astronomy was his grand revival of the heliocentric hypothesis as a systematic planetary theory<sup>1</sup>. But in order to fit theory to observations, Copernicus had retained the geometric devices used by Ptolemy (the deferent, epicycle and excentric), and had referred details of planetary movements not to the Sun but rather to the centre of the Earth's orbit. Because of technical and other difficulties with the copernican system, the astronomer Tycho Brahe (1546–1601) rejected it. Brahe had compiled an unrivalled set of observations, which he thought would demonstrate that the Sun and Moon travel around the Earth while the other planets travel round the Sun<sup>10</sup>.

After Brahe's death, Johannes Kepler (1571–1630) invested years in the analysis of Brahe's data, culminating in the derivation of Kepler's three laws of planetary

motion. These provided a precise and enduring mathematical characterization of the heliocentric hypothesis, thus serving to support the position of Copernicus while ironically refuting that of Brahe.

STUART HALE SHAKMAN

## CFC photolysis

SIR—It is certainly possible (*Nature* **338**, 100; 1989) that "the great Antarctic ozone hole is a place where [CFCs and their products are] washed out on to the ice-cap". But this is not the rate-limiting factor in the very long tropospheric lifetimes of CFCs. The rate-limiting factor is simply the rate at which CFCs are carried up into the stratosphere to be photolysed. The sites of this photolysis are the middle and high stratosphere outside the polar night, not the ozone hole; and all the evidence points to the conclusion that this rate is controlled by atmospheric dynamics and that it is not particularly sensitive to details of how and where photolysed material returns to the troposphere. If anything, the throughput could be a little weaker in strong ozone-hole years.

## Status of science

SIR—I agree with the gist of your leading article "Science squeezed" (*Nature* **338**, 1; 1989) on the shortage of young researchers in Britain. Research should be shown to be an honoured as well as an honourable profession, but the salaries paid by the state are surely indicative of the public's view of the comparative standing of the profession, as we have recently seen in the case of nurses.

I would like to take hospital physicists as an example of the standing of scientists. They have recently accepted, under duress, a pay rise of only 5.5 per cent, whereas the medical profession has been awarded a rise of more than 8 per cent. This is a fairly typical experience for scientists employed by the National Health Service and the story could probably be repeated in other

countries. I realize that hospital physicists are not predominantly engaged in research, but the country is tragically short of physicists in many areas. It is not surprising that there is now a substantial shortage of hospital physicists, yet the British public was only recently outraged when the calibration of an instrument used for radiotherapy in a hospital was wrongly set.

Lord Zuckerman, in *Scientific American* (September 1988, page 106), said that the most important element in the role of the scientific adviser to the chief executive (president or prime minister), is to "advise . . . on whether or not the country's educational institutions are turning out enough adequately trained manpower to fill the jobs that determine the well-being of the nation. A president, . . . has to feel confident that everything that can be done to satisfy this objective is being done, given the resources that can be made available." There is no evidence that this is happening in Britain.

## Reprint research

SIR—Previous correspondents have argued for and against the reprint system, but have provided very little information about the pattern of reprint requests. You may therefore be interested in the sources of requests for reprints of my paper "Population dynamics of starlings in New Zealand" (*N.Z. J. Ecol.* **4**, 65–72; 1981). Starlings, being cosmopolitan, should interest all countries; publication yielded a nice collection of stamps and the following tally: United States 24, Canada 4, Finland 4, France 4, Japan 4, Hungary 3, Spain 3, Sweden 3, Australia 2, Belgium 2, Czechoslovakia 2, East Germany 2, West Germany 2, Israel 2, Poland 2, Alaska 1, Denmark 1, Italy 1, Latvia 1, Mexico 1, South Africa 1, Soviet Union 1, United Kingdom 1.

Given these data, one may speculate. Has the Soviet Union 24 times as many Xerox machines as the United States, or has the United States 24 times as many starlings? What does the United States do with all these reprints when it is said that Americans never quote overseas literature? If only one in 24 Soviets reads English, what do the English read? The intense rivalry between East and West Germany is mirrored in the exactly similar number of reprint requests, but why the balance between Latvia and Mexico? Finally, look at New Zealand: 3 million people, and none could afford the stamp.

# Complicated problems not yet soluble

While physics may remain the art of representing difficult problems as simple, even the simplest complicated problems appear to have the practitioners bemused.

EVERYBODY knows by now that physics is merely sleight of hand. Very few problems of the real world are exactly soluble, and then only because it has been possible to simulate the real by a much simpler problem. The whole of kinetic theory is nothing more than an account of the motion of billiard balls, or elaborations thereof. The vibration of a turbine blade in a jet engine is described in terms of what is essentially the motion of a pendulum, as if it were just another example of simple harmonic motion.

That it may be far from simple to tell from first principles what are the frequencies of vibration of a turbine blade only serves to illustrate the point: the most widely used techniques are in at least two senses approximate — the predicted frequencies of vibration will be more or less in error and, even more significant, the only certainty is that any finite list of vibration frequencies must be incomplete.

This state of affairs is widely if not ostentatiously acknowledged. If challenged, people will readily turn the question against those who ask it, saying that the simulation of so many complicated by so few simple problems is a measure of the sophistication of their craft. But the business of chaos is a reminder that not everything is dealt with simply.

Even apparently simple dynamical systems capable of simple harmonic motion will behave unpredictably if, for example, there are forces which are not proportional to the displacement or some time-derivative of it. But while such a motion may be complicated, the same cannot be said of the underlying system, which has only two degrees of freedom (one space coordinate and time). That is the dark side of the claim that physics is the craft of making complicated problems simple: the search for simplicity blinded people to complexity.

The study of truly complicated systems is another matter, but the past few years have seen their surreptitious accumulation. These are the problems with many degrees of freedom in which the multiplicity is of the essence.

A simple regular idealized crystal lattice is a good illustration. If there are  $N$  atoms at the lattice points,  $3N$  coordinates will be needed to specify their displacements from their equilibrium positions and there will be  $3N$  frequencies of vibration which, once calculated, will describe the vibration of the crystal as if it were the vibration

of any one of  $3N$  oscillators.

But if the lattice points are occupied by quantum spins (as in, say, a ferromagnet), and if the problem is to calculate the response of the system to an external field, there is no such route to simplicity. The state of all spins at each instant is essential to an understanding of how the system as a whole behaves. Ways of approximating to an understanding by what are called, for example, 'mean-field' approximations, may yield gross measures of, say, magnetization — but then only well away from the Curie temperature. Subtle features of such a system, say the speed of motion of the boundaries between magnetized-domains, for example, remain incalculable.

The recently accumulated examples of this kind keep many people awake at night. Neural networks are a fashionable example, where the instantaneous state of all the neurons in an interconnected network is crucial to an understanding of how one state of the network switches to another. But that is merely one reason for remarking that, against the prevailing grain of physics, there appears from the literature to be a small group of people working away at systems which, by having many degrees of freedom, are inherently complicated, but which are nevertheless tractable.

There is, for example, the case of the proposed use of arrays of interconnected superconducting Josephson junctions as means of analysing the frequency of millimetre-wave signals. Kurt Wiesenfeld and Peter Hadley from the Georgia Institute of Technology have now given a fascinating account of this system (*Phys. Rev. Lett.* **62**, 1335; 1989). Those interested will find an earlier preliminary account (with M.R. Beasley) helpful in fixing ideas, as the saying goes (*Appl. Phys. Lett.* **52**, 1619; 1988).

A Josephson junction is a two-dimensional superconducting circuit (on a chip) whose dimensions are such that the wavefunctions of the circulating electrons have dimensions comparable with those of the whole device. One consequence is that the electrical behaviour of a single junction in an array is determined by the phase difference between its electronic wavefunction and that of neighbouring wavefunction. Josephson junctions, in other words, are a means of making quantum properties macroscopically measurable. Arrays can be fabricated with a difficulty that may

seem child's play to those who make fortunes in the semiconductor industry.

But to make such arrays function as advertised in the millimetre-wave business, all the junctions in an array must oscillate together, in phase with one another. The difficulty is that the equation that determines the oscillation of a single junction in an array is inherently non-linear. (Apart from a few constants, the quantity representing the restoring force in simple harmonic motion appears as the trigonometric sine of that quantity, and there is no presumption that the equivalent of the restoring force is small, because the argument of the trigonometric sine can be anywhere between 0 and  $2\pi$ .) The consequence is the sequence of *ad hoc* arguments by which the authors reach their interesting conclusion.

This is how it goes. It is easy enough to show that the condition in which all the junctions in an array oscillate as one, with no phase differences between them, is a solution of the equations; that is why arrays of Josephson junctions were advocated as local oscillators in the first place. The practical question is whether such an oscillating state will be stable. Bereft of more explicit alternatives, the authors go through a counting exercise, adding up the number of oscillatory states of a Josephson array in which the phases will be out of synch.

The obvious practical question is whether the discriminatory power of a local oscillator built on lines like this will increase as the number of junctions in the array increases. Naturally, there must be a tendency in that direction, but there is also a countervailing influence. Put crudely, each out-of-synch state of oscillation is potentially a state into which the intended stable state may be kicked by random noise — and the out-of-synch states are crowded ever more closely together (in what is known as phase space) as the number of elements increases. A further consequence, demonstrated only by numerical simulation, is that an increase in the number of elements in an array quickly decreases (virtually to zero) the time an array will spend in any particular oscillatory state.

On the face of things, that would seem to spell the end of Josephson arrays as millimetre-wave detectors, but really it is merely a signal that much more needs to be learned of a complicated simple system.

John Maddox

# Defective viruses to blame?

Robin A. Weiss

THREE new papers on an acquired immune deficiency syndrome in mice caused by a strain of murine leukaemia virus suggest that a defective genome is responsible for the immunodeficiency. Janet Hartley, Sandy Morse and colleagues<sup>1</sup> at the National Institutes of Health have found an unusual pattern of genetic susceptibility to murine AIDS consistent with a defective genome being carried by different replication-competent 'helper' viruses. This has been followed up by the molecular identification, also by Hartley and colleagues<sup>2</sup>, of the defective virus. And an apparently identical genome has been independently identified by Paul Jolicoeur and colleagues in Montreal, as they report on page 505 of this issue<sup>3</sup>. After cloning of the defective virus, which retains *gag* sequences in its 4.8-kilobase genome, and rescue by non-pathogenic helper viruses, inoculation into mice leads to the induction of AIDS<sup>2,3</sup>. These findings supplement that from Jim Mullins's group<sup>4</sup> which shows that in cats, immunodeficiency can be caused by a defective feline leukaemia virus.

Many classes of animal RNA virus accumulate defective variants when propagated serially at high multiplicities of infection. This was first observed by von Magnus with influenza virus<sup>5</sup>. Such defective viruses frequently interfere with the replication of full-length, non-defective genomes and they may play a role in pathogenesis and persistent infection<sup>6</sup>. Defective retroviruses, however, do not typically interfere with their helper viruses and are not simply truncated forms of the competent virus; they contain recombinant viral or cellular sequences that can directly influence the pathogenesis of the virus population.

## Retroviral oncogenes

The notion that defective variants of retroviruses cause specific disease was raised more than 25 years ago, when Hanafusa *et al.*<sup>7</sup> showed that the Bryan strain of Rous sarcoma virus was defective. This classical study led eventually to the identification of oncogenes derived from cellular genes, usually by insertion at the expense of viral genes, thereby rendering the viral genome replication-defective. Nearly all retroviral oncogenes are carried in defective viruses requiring helper viruses for transmission.

That defective retroviruses can carry 'scrambled' viral genes determining new disease patterns, rather than cellular genes, was first seen with the spleen-focus-forming virus (SFFV) component of Friend erythroid leukaemia virus. The defective SFFV genome encodes an incomplete

retroviral *env* gene derived from exogenous, 'ecotropic' and endogenous, 'xenotropic' sequences. This new form of glycoprotein probably interacts with specific 'dual-tropic' receptors on erythroid precursor cells to trigger their proliferation<sup>8</sup>. As the term 'viral oncogene' is usually restricted to gene sequences of mainly cellular origin, and of course pertains to those genes inducing neoplastic transformation, we need a new term for retroviral genes of viral origin specifying particular disease forms — I would offer as a suggestion 'pathogenes' with path as the generic equivalent to onc.

The SFFV gene determining erythroid leukaemia is derived from *env* sequences<sup>8</sup>, as is the gene inducing feline AIDS in defective feline leukaemia virus<sup>4</sup>. A recent paper by Poss *et al.*<sup>9</sup> indicates that the property of the *env* protein of the defective feline AIDS virus which makes it cytopathic for T cells lies in its post-translational glycosylation pattern. With murine AIDS, however, it appears that the functional path gene in the defective virus is derived from the *gag* gene. Aziz, Hanna and Jolicoeur<sup>3</sup> have sequenced the 4.8-kilobase genome and found four open reading frames, two corresponding to portions of *gag*, one to part of *pol* and one to part of *pol-env*.

The p12 region of the largest open reading frame (586 amino acids) has only 40–50-per-cent identity with Gag p12 of other murine retroviruses, and it is this product that the authors suspect is responsible for inducing AIDS. Chattopadhyay *et al.*<sup>2</sup> also implicate a *gag*-related product because Gag antisera including anti-p12, but not anti-Pol and anti-Env sera, immunoprecipitate a 60-kilodalton protein from a murine cell line carrying the defective genome in the absence of helper virus.

The study of defective murine and feline leukaemia viruses causing immune deficiency syndromes should enhance our understanding of the various ways retroviruses induce disease. Being oncoviruses rather than lentiviruses and therefore less closely related to the human immunodeficiency virus (HIV), their use in screening anti-viral drugs is doubtful; if one wishes to use an oncovirus for this purpose, Friend virus induces disease in mice more quickly with a more quantifiable endpoint.

Aziz *et al.*<sup>3</sup> cite striking similarities of murine AIDS to human AIDS, though there are striking differences too. The disease was first described as lymphoma<sup>10</sup>, owing to what is now believed to be a polyclonal B-cell hyperplasia rapidly induced by the virus. A detailed study<sup>11</sup> of

the syndrome showed that a profound suppression of humoral and cellular immunity soon follows the lymphoproliferative phase. Both the B-cell hyperplasia and the immune suppression seem to be T-cell dependent, because the virus affects nude mice much less severely<sup>12</sup>. However, it is not clear that the virus infects T-helper cells, and the macrophage reservoir and neurotropism characteristic of HIV have not been examined in murine AIDS. In my view, the diseases induced by HIV-related, T-lymphotropic lentiviruses of cats (FIV), cattle (BIV) and monkeys (SIV) will prove to be more proximate models of human AIDS.

## Role in human AIDS

Nonetheless, the discovery of defective oncoviruses inducing severe immunosuppression in cats and mice raises the question whether defective HIV genomes might play a role in human AIDS. Replication-competent, molecularly cloned HIV and SIV genomes have not yet been shown to induce AIDS, and even if they do, that might require the generation of defective, variant genomes during the long incubation period between infection and manifestations of disease.

Several HIV laboratories are finding a myriad of viral forms when sequences are amplified directly from infected tissues, rather than selecting for replication-competent viruses in cell culture. Simon Wain-Hobson (personal communication) refers to such HIV populations as 'quasi-species' because they represent greater diversity than might be expected from classical population variability. The mixture of defective oncoviruses and the helper viruses required for their generation and transmission represents a special case of quasi-species genome dynamics. No doubt defective forms of HIV will be carefully scrutinized at the molecular level. □

# Global perspectives of chaos

Christopher H. Scholz

RECENT developments in nonlinear dynamics have not failed to capture the imagination of geophysicists, whose domain encompasses a great many nonlinear processes. For solid-Earth geophysicists, the most exciting possible applications are to mantle and core convection and, especially, earthquakes. Any segment of the stressed boundary between two plates exhibits a seismic cycle defined by the recurrence of large earthquakes, between which only minor seismic activity occurs. In many cases, this cycle does not seem to be periodic, but the question "is the system chaotic, and if so, in what way?" is yet to be resolved.

Condensed matter physicists and geophysicists came together at a recent meeting\* to discuss such questions. Each group is still learning the other's discipline, so that what transpired was a preliminary dialogue which nonetheless contains a foretaste of things to come.

The elastic rebound theory of earthquakes, developed by H. F. Reid at the turn of the century, is often inferred to predict the periodic recurrence of large earthquakes, but even in Reid's day it was recognized that the spatial heterogeneity of faults would result in aperiodic behaviour (G. K. Gilbert, *Science* **29**, 121-138; 1909). The seismic cycle can be thought of as a friction-damped oscillator with many spatial degrees of freedom, which is almost a prescription for chaos. As symptoms of this, it is already known that the system abounds in fractal distributions. The Gutenberg-Richter power-law size distribution of earthquakes, as near to universal as any geophysical observation, is one such fractal distribution, and it has also been found that the size distribution of faults, fault topography and even the grain-size distribution of fault gouges are fractal (D. Turcotte, Cornell University; C. Sammis, University of Southern California). Earthquake faults thus have the same fractal nature as other fractures, as discussed in a recent News and Views article by Robert Cahn (*Nature* **338**, 201; 1989).

The seismotectonic system can be regarded as a nested hierarchy of fractals, ranging from topography produced by active faulting down to the material

ground between the fault walls. Although they have learned these geometric facts, geophysicists have only just started to think about the dynamic systems that can give rise to such structures. Any models developed in other fields of nonlinear science, such as those employing cellular automata or renormalization groups (discrete-variable approximations of differential equations), are ripe to be imported to explain the physics of earthquakes.

Although most nonlinear studies to date have been of low-dimensional systems, a very general model of spatially extended dissipative systems has recently

contrast, another cellular-automata model employing simple triggering criteria (T. Hirata, Tsukuba University) has the property that even if started randomly it becomes organized by phase-locking to produce regular large events. Earthquakes may have both of these characteristics. Large earthquakes must roughen the stress distribution on the fault, but in the intervening period, many small earthquakes must smooth it again to set the stage for the next large event.

Whereas the periodicity of the earthquake cycle is a central question for long-term earthquake prediction, short-term prediction depends on identifying the nucleation phase. Diffusion-limited-aggregation and viscous fingering models of nucleation (T. Halsey, University of Chicago; W. Klein, Boston University)

are instructive but not very applicable, as their finely branched structures are unlike earthquake rupturing, which tends to fill the plane. The several forms of a renormalization group model of bundles of parallel fibres under tension produce a chain-reaction nucleation (S. Solla, AT&T Bell Laboratories; W. Newmann, University of California, Los Angeles), but have the unfortunate property of predicting zero strength in the limit of an infinite bundle. This is because the entire bundle fails when the weakest fibre does, owing to the strong nearest-neighbour reloading.

Ropemakers long ago learned to avoid this property by braiding the rope,

which causes friction between strands to be induced by tension on the rope; this causes the problem to become three-dimensional because a broken fibre does not globally lose its load-carrying capacity. Earthquakes, being shear cracks, dissipate energy by friction over their entire surface and so will similarly have a less abrupt nucleation. Nucleation models based on rock friction constitutive laws exhibit scaling that depends on a critical slip distance (J. Dieterich, US Geological Survey, Menlo Park). The critical slip distance is a material (surface) property, which in uniform block-slider models determines the size of the slipping patch at instability (see my paper in *Nature* **336**, 761-763; 1988). However, in spatially extended models in the stable mode, chaotic motion can occur with this friction law, even in the case of spatially uniform parameters (F. Horowitz, Georgia Technical College). This may avoid a problem that seemed implicit in the model: the prediction of a minimum earthquake size.

been developed which predicts some of the characteristics of earthquakes (P. Bak, C. Tang & K. Wiesenfeld, *Phys. Rev. A* **38**, 364-374, 1988). This cellular-automata model has the property that it evolves to a self-organized critical state that is characterized spatially by a power-law size distribution of clusters and temporally by  $1/f$  noise ( $f$  is frequency). A simple visualization of it is of a pile of sand, in which the self-organized critical state is the maximum angle of repose, the size distribution of landslides is a power-law, and the sand flow off the pile is  $1/f$  noise. Earthquakes do have this size distribution, and the temporal signature can be checked by the study of earthquake catalogues.

Building further on this development is a model of a network of stick-slipping friction masses connected by springs (J. Langer, University of California, Santa Barbara). This model has the important property that even if it is started in a homogenous state it evolves to chaos. In

\* Earthquakes: chaotic or deterministic? Asilomar, California, 12-15 February 1989.

The origin of the fractal topography of faults was addressed by H. Herrmann (Saclay). In a square-grid model subjected to shear forces, crack growth occurs with pervasive branching, resulting in a fractally irregular crack traversing the grid with many side branches. In contrast, the tensile case produced a much more regular structure, with only minor secondary cracks. This result, not likely to be sensitive to the details of the model, explains the much greater complexity of shear to tensile cracks that is well known from both the field and laboratory.

In two other papers not related to earthquakes, modelling predicted chaotic behaviour for diverse phenomena. Volcanic (harmonic) tremor is a nearly continuous vibration that accompanies volcanic eruptions. Treating the source of the vibrations as magma flowing through a compliant crack, B. Julian (US Geological Survey, Menlo Park; see figure) finds that including radiative dissipation introduces a transition to chaos by 'period doubling': as the magma velocity approaches a critical

value, sub-harmonics of the vibration set in until the vibration becomes completely chaotic. And the onset of chaos by way of 'Hopf' and 'pitchfork' bifurcations, splitting of fluid trajectories, has been predicted in models of mantle convection (C. Stewart, Cornell University).

There are sophisticated methods for extracting from a time series of a chaotic process the structure of the 'attractor' (which defines the set of possible states), after which one has a better chance at guessing the system that produced the attractor (J. Sidorowich, University of California, Santa Cruz). But the question for earthquakes is whether geophysical data sets are adequate for this approach. Seismicity catalogues are generally much shorter than the recurrence time of large earthquakes, and it is not at all clear that the attractor for the loading cycle can be obtained from them. □

Christopher H. Scholz is at Lamont-Doherty Geological Observatory, Palisades, New York 10964, USA.

can capture the available neurotransmitter and thus more pores can be opened (the postsynaptic mechanism). An increase in transmitter release might also occur by having each vesicle contain a greater quantity of neurotransmitter. On the postsynaptic side, an increase in strength could also result if each pore remained open for a longer time or if each receptor were to bind its ligand more avidly.

The question, then, has been whether LTP arises from a presynaptic mechanism (more transmitter release) or a postsynaptic mechanism (greater sensitivity of the target membrane). The second alternative, the postsynaptic mechanism, is easiest to believe because it is well established that the crucial signal for triggering LTP (a postsynaptic influx of calcium ions) occurs only in the postsynaptic neuron. Nevertheless, until recently, the weight of evidence favoured the presynaptic mechanism and one was forced to suppose that the triggering signal produced another message that was relayed from the target neuron back to the axon terminal. What Davis *et al.* are proposing is even more complicated.

One good way of detecting a postsynaptic mechanism is to apply neurotransmitter locally to the target neuron and see if it is in fact more sensitive after heavy synaptic use than before. If synaptic strength correlates with postsynaptic sensitivity to neurotransmitter, determined by direct glutamate application, then the mechanism is probably at least partly postsynaptic. If, on the other hand, the postsynaptic membrane is not more sensitive to exogenously applied neurotransmitter, either LTP arises through an increase in transmitter release, or the experiment is inconclusive because the right place on the postsynaptic neuron was not tested.

What Davies *et al.* find is that, even though LTP develops promptly after heavy synaptic use, postsynaptic sensitivity to exogenously applied neurotransmitter (more correctly, to a neurotransmitter analogue) develops slowly over about half an hour. The conclusion, then, is that the mechanism is presynaptic for the first half-hour and that gradually the postsynaptic membrane becomes more sensitive — some signal must pass from the postsynaptic membrane to the axon terminal to produce a transient increase in release. With

time, however, an increased sensitivity of the postsynaptic membrane grows so that LTP is maintained by a postsynaptic mechanism.

Although this mechanism seems complicated, it does fit with other recent observations. Kauer *et al.*<sup>2</sup> were the first to define clearly two temporal phases of LTP — they discovered a first, transient LTP component that lasts about half an

## LONG-TERM POTENTIATION

# Strengthening the synapses

Charles F. Stevens

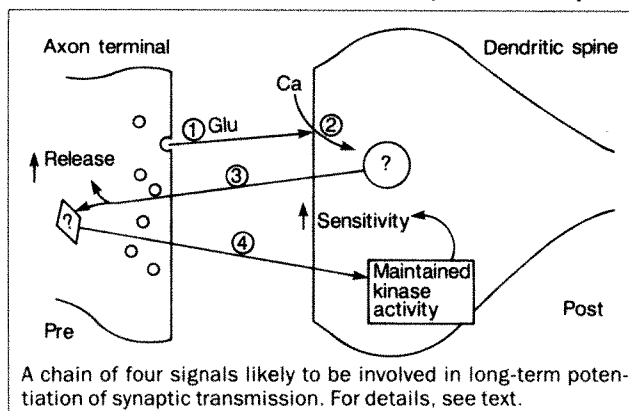

ON page 500 of this issue<sup>1</sup>, Davies *et al.* provide an answer to one of the important open questions about how long-term potentiation (LTP) works. LTP is a very long lasting increase in synaptic strength that is produced at certain synapses when they are used repeatedly — a sort of microscopic 'practice makes perfect'. This phenomenon has attracted much attention recently because it is thought to be the cellular basis for certain types of memory.

Whether the site of increased connection strength is presynaptic or postsynaptic — that is, whether it resides in the sending or the receiving neuron, has been a controversy for some time. The answer Davies *et al.* give is more complicated than most had hoped for: it is both. For the first half-hour after a synapse has been heavily used, the increased strength arises in the presynaptic terminal, and then the processes causing LTP develop in the postsynaptic membrane.

Just how can a synapse get stronger? Understanding the possibilities requires a brief review of how synapses function. Synaptic transmission works by the nerve terminal (the presynaptic element) releasing neurotransmitter through an exocytotic process. In the synapses where LTP has been demonstrated, this is glutamate, which is contained in 40-nm vesicles that are released into the cleft between the pre- and the postsynaptic

cells; the glutamate diffuses rapidly across the cleft and binds to several distinct types of glutamate receptors in the membrane of the target neuron (the postsynaptic element). These receptors open pores through which ions flow. Synaptic strength, then, is determined by the quantity of ions that flow through open pores into the postsynaptic neuron.

A synapse will be stronger if more neurotransmitter is released by the axon

terminal or if the postsynaptic neuron responds more vigorously to whatever quantity of transmitter is present, or both. The two possibilities that are usually considered are: first, that the axon terminal releases more vesicles, each containing a fixed quantity of neurotransmitter (the presynaptic mechanism for strengthening); or second, that the target postsynaptic membrane contains more receptors than

## GEL ELECTROPHORESIS

## DNA molecules observed

Ted Richards

hour, the same duration as the presynaptic phase of LTP now defined by Davies *et al.*. This transient component can be evoked in isolation by applying neurotransmitter directly to synapses without stimulating the axon terminals<sup>2</sup>.

More recently, Malinow *et al.*<sup>3</sup> have discovered a second way to define transient and maintained phases of LTP. A persistent speculation has been that one fundamental mechanism in the storage of memories is the covalent modification of some (unidentified) proteins by kinases. During an investigation of this hypothesis, Malinow *et al.* found that when kinases are inhibited, the transient phase of LTP is still evoked, but that the maintained phase fails to develop. According to the new results of Davies *et al.*, the transient phase of LTP would be presynaptic, and the maintained component would result post-synaptically from an increased sensitivity of receptors to neurotransmitter resulting from some kinase activity.

All this work has many potential sources for artefacts. If the results are taken at face value, though, the following picture of four inter-related signals emerges (see figure). The first is glutamate that is released from the axon terminal and acts on the postsynaptic membrane to change the postsynaptic voltage and — under the right circumstances — permits an influx of calcium ions. The resultant change in postsynaptic calcium concentration constitutes the second signal and produces, by an unknown mechanism, the third signal that is sent from the postsynaptic cell to the axon terminal where it increases the quantity of glutamate released for each nerve impulse that arrives.

This third signal, in conjunction with some trace of recent heavy use of the axon terminal (calcium again?), causes the fourth signal to be passed from the axon terminal back to the postsynaptic target neuron where it somehow produces a maintained kinase activity that, in turn, results in an increased postsynaptic sensitivity to glutamate.

Why is such a complicated scheme needed? One reason may be that the brain wants to be very careful to store only valid memories, and therefore needs to be sure that parts of the system are not activated accidentally. By having this 'handshaking' scheme, checks are instituted to ensure that the necessary conditions are met for having an appropriate increase in synaptic strength. Whatever the reason, there is clearly still much to learn about the mechanisms involved. □

Charles F. Stevens is in the Section of Molecular Neurobiology, Yale University Medical School, New Haven, Connecticut 06510, USA.

3. Malinow, R., Madison, D.V. & Tsien, R.W. *Nature* **335**, 820-824 (1988).

It should be obvious to any reader of *Nature* that gel electrophoresis of DNA has revolutionized molecular biology. It is therefore odd that the precise mechanism whereby DNA molecules, moving under the influence of an electric field in a gel, are separated according to their length, is but poorly understood. The standard description, based on the reptation model of De Gennes, has the molecule snaking down a 'tube' among the gel fibres with the head moving in a direction biased in the direction of the field. This model accounts for the observed inverse relation between mobility and molecular size, which breaks down for long molecules or

toy which consists of a squat helical spring that 'walks' down stairs.

The picture is broadly similar at low-strength fields, but here coils may also start to form in the middle of the extended chain; these may work their way to the trailing end of the chain as the front moves down the field. When they reach the end the trailing end may take off downwards, so forming an inverted 'U' with the chain looped over several obstructions. Eventually the longer end pulls the chain free.

Smith *et al.*<sup>3</sup> and Schwartz and Koval<sup>2</sup> describe experiments in which the motions of real DNA molecules are directly observed. The idea is novel but

Movement of a DNA molecule in an electric field. *a*, The molecule is aligned along the field with end B leading. *b*, The field is reversed and the chain is starting to align in the new direction. The centre of mass has not moved downwards. *c*, The molecule is now aligned in the new direction with end A leading. It can now start to move.

at high electric fields when the mobility is found to be independent of size. It now seems, however, that this model is oversimplified. Deutsch and Madden<sup>1</sup> have now described a computer simulation of the movement, a study which is complemented by experimental observations of real DNA molecules by Schwartz and Koval on page 520 of this issue<sup>2</sup> and by Smith *et al.* in a paper recently published in *Science*<sup>3</sup>.

Deutsch and Madden model the DNA molecule by a chain of charged beads and the gel matrix by a rectangular array of obstructions. They set up equations which determine the motion of the beads and solve these numerically on a computer. In this way they obtain a series of 'snapshots' which portray the conformations of typical chains as time progresses. The results unexpectedly show that a chain alternates between a coiled conformation and one in which the chain is extended in the direction of the field. Exactly what happens depends on the field strength.

Starting at the stretched-out phase, Deutsch and Madden find for high-strength fields that the leading end starts to coil up, eating up the rest of the chain as it moves down; this coil becomes entangled with the gel obstructions. Then one end proceeds to move down leaving the other looped over the gel fibres. As this leading end moves in the direction of the field, the loops slip off the obstructions, until eventually the trailing end is freed and the cycle starts again. The whole cyclic motion is reminiscent, to those who have seen it, of the motion of a 'slinky', a

simple. The DNA molecules are first labelled with a fluorescent dye and then allowed to migrate in an electric field in a thin layer of agarose on a microscope slide. When the specimen is illuminated with light of a suitable wavelength, the fluorescing groups reveal the conformation of the DNA chain. The image of the wriggling chain can be recorded on video tape. The motions so recorded by both groups are in good qualitative agreement with the simulations obtained by Deutsch and Madden, and at some variance with standard reptation model.

Deutsch and Madden<sup>1</sup> discuss the assumptions inherent in the reptation model which appear to be violated in their simulations; they also show that the mobility of long chains in high electric fields is independent of the chain length, in agreement with both standard reptation theory and experiment. This effect leads to an experimental impasse whereby any DNA chain longer than about 20 kilobases cannot be resolved using conventional methods. This impasse is much to the chagrin of molecular biologists, who wish to resolve ever larger pieces of DNA, up to the ultimate goal of separating whole eukaryotic chromosomal DNA.

Several groups have found ways out of this impasse by periodically altering the direction of the field. In this way it is now possible to resolve molecules the size of the yeast chromosome, about 2 megabases. Several such methods involve fields oriented at an obtuse angle to each other so that molecules traverse a zig-zag path along the bisector of this angle. The

reptation model provides a schematic picture of how this works (see figure): at each change in field orientation, both ends of the chain move off in the new direction. Only after a certain time, dependent on the length of the chain, is a molecule completely oriented in the new direction; this process must be completed before further net progress is made. Thus longer molecules are retarded more than shorter ones. This mechanism does not explain all the experimental results, particularly those in which the field is periodically reversed.

The simulations of Deutsch and Madden contain some artificial features: they are conducted in two rather than three dimensions (which may not be serious), and the rectangular array of

obstructions cannot correctly mirror the true structure of the gel, which is largely unknown. Further work should ameliorate these difficulties and also suggest what happens when the direction of the field is changed. Nevertheless, it is hoped that these insights and observations will stimulate experimentalists to devise methods of resolving longer and longer DNA chains. □

## CRYSTALLIZATION

# Views of interfacial ephemera

A. Lindsay Greer

QUANTITATIVE measurement of crystallization kinetics in alloy systems has become possible in recent years through the annealing of metallic glasses. In the glasses the atomic mobility is sufficiently low for the rates of crystal nucleation and growth to be measurable and for the sample temperature to remain uniform during the reaction. These are conditions which do not apply in the more common case of crystallization from a liquid. Newly reported work by Sutton *et al.*<sup>1</sup> shows that important information on the structural changes during crystallization of a metallic glass may be lost if the experiment is not conducted in real time during the anneal. The transient interfacial phases suggested in the new work merit further study because of their potential significance in understanding crystallization kinetics not only in glasses, but also in liquids.

In conventional structural studies of the crystallization of metallic glasses, X-ray diffraction experiments are performed at room temperature after annealing. In contrast, Sutton *et al.*<sup>1</sup> use synchrotron radiation to study the transformation *in situ*, with time resolution of 3 ms. The study is of the formation of the body-centred tetragonal phase of NiZr<sub>2</sub> from metallic glass of the same composition. Diffraction patterns from the partially transformed samples cannot be reproduced by superposing the patterns from the initial amorphous phase and from the final NiZr<sub>2</sub>, so that the authors postulate there is a precursor phase. It has broad diffraction maxima and is a transient structure existing at the interface between the growing-crystal phase and the amorphous phase. As shown in the figure, the phase is most noticeable in the early stages of the transformation. It is found only during anneals at higher temperature when the transformation is more rapid.

That metallurgical transformations can proceed through intermediate stages (rationalized, for example, by Turnbull's step-entropy rule<sup>2</sup>) is well appreciated, and is exploited in the conventional practice of quenching and annealing, as in the production of precipitation-hardened alloys. The annealing is stopped before

The time dependence of the total crystalline volume fraction (a) and the volume fraction of intermediate crystalline phase (b) for an anneal of NiZr<sub>2</sub> metallic glass at 680 K (redrawn from ref. 1).

the final equilibrium is reached, to preserve the intermediate microstructure which is technologically useful.

But the possibility of an intermediate phase that exists only during the reaction and that cannot be preserved by cooling is not commonly considered. Such a concept is related to the activated-complex or transition state used in considering the mechanisms and rates of chemical reactions. For crystallization, a first-order transformation, any intermediate state must be associated with the interface between the two phases. One instance where a transient interfacial phase has previously been postulated<sup>3</sup> is the explosive crystallization of thin films of an amorphous semiconductor, such as germanium, which is explicable only if

there is a thin layer of metallic liquid, maintained by the release of latent heat, at the interface between the solid amorphous and crystalline phases, both of which have covalent tetrahedral bonding.

The nature and origin of the possible transient phase in the crystallization of Ni–Zr glass must be very different, but likewise it may be significant in analysing crystal growth. The attachment of atoms to a crystal growing in a liquid or amorphous phase may involve diffusive jumps, leading to a maximum, diffusion-limited growth velocity of around 10 m s<sup>-1</sup>. But measurements of dendrite velocities in undercooled melts led Turnbull<sup>2</sup> to suggest that for pure metals, the crystal growth rate may be limited only by the collision rate of atoms with the interface. The collision-limited growth rate would then be near the speed of sound, about 200 times the diffusive speed. From pulsed laser experiments, there is firm evidence for each type of growth; collision-limited for pure metals<sup>4</sup>, but diffusion-limited for intermetallic compounds<sup>5</sup>. The transition from one type of growth to the other as the solute content is increased has not yet been satisfactorily analysed.

Sutton *et al.*<sup>1</sup> suggest that the transient phase is a poorly ordered version of the final crystalline structure. Thus there is evidence for growth proceeding in two stages, crystallization followed by chemical ordering, in a manner consistent with the step-entropy rule. Diffusion-limited growth may arise when there is a need for rearrangement of the atomic short-range order at the interface, and just such a process may be revealed by the *in situ* study. The transition between types of growth may be elucidated by studies of the same type on growth of extended elemental solid solutions and of intermetallic compounds with different structures.

The greater fraction of intermediate phase detected at higher temperatures could reflect, as the authors suggest, the higher nucleation frequencies and greater interfacial areas during the transformation. On the other hand, it is possible that it could be associated with the ordering lagging further behind the faster interface. A transition from growth of an ordered phase to growth of a disordered intermediate could affect not only the growth rate, but also the degree of faceting of the crystal through the well-known link with entropy change across the interface<sup>6</sup>. □

## EPSTEIN-BARR VIRUS

# Chance and felicity

John Galloway

TWENTY-five years ago this week the first report appeared of what came to be known as Epstein-Barr virus (EBV)<sup>1</sup>. The finding of a previously unknown virus in tumour cells cultured from a patient with (Burkitt's) lymphoma was a signal event for the Cancer Research Campaign (CRC), then the British Empire Cancer Campaign, and one that the campaign is celebrating next week with an international conference\*.

The progress of science is littered with happy coincidences, chance observations and meetings that mark the beginning of successful lines of research. But few have involved as much serendipity in their early stages as EBV. The story began in the 1950s when Denis Burkitt noticed a child in the African teaching hospital where he worked with swelling in all four quadrants of the jaw. It seemed to be neither a tumour nor an infection, but three weeks later he saw exactly the same thing again in another patient. No longer a curiosity, the condition became a medical problem, and in time it was realized to be the commonest childhood cancer in Africa — and indeed that other childhood lymphomas were simply different manifestations of the disease — now called Burkitt's lymphoma.

Burkitt noticed that the disease had a characteristic geographical distribution, clearly related to climate. Climate sugges-

ted biological transmission, possibly an insect vector. He turned out to be right about the climatic connection — his lymphoma had exactly the same geographical distribution as malaria — but not about the insect vector. His work attracted little interest until he gave a lecture in 1961 which was attended by Tony Epstein.

Epstein, Barr and Achong in 1964 (courtesy of M. A. Epstein).

Epstein, persuaded by Burkitt's argument for a biological cause, decided it must be an oncogenic virus<sup>2</sup>. Viruses were known to cause and spread cancers in animals, and, although there was really no evidence, were thought to cause human cancers.

At this point the Campaign paid for Epstein to visit Burkitt in Kampala to obtain biopsy material. In a cell line established in culture from a tumour biopsy, they found, using the electron microscope, a new, large, icosahedral herpes-like virus in the tumour cells. The finding was reported in *The Lancet* and was later named after Epstein and his PhD student Yvonne Barr who, with Bert Achong, was

his co-author. It was fortunate that the laboratory had available thin-section electron microscopy; the virus could not have been detected otherwise as it was inactive in all the biological assays then available.

The serendipity which marked the early work on EBV was repeated later in the Henles' laboratory in Philadelphia, where a chance event revealed that EBV was also the cause of infectious mononucleosis — glandular fever. A technician whose blood was being used as a negative control in serum-antibody tests for EBV infection contracted glandular fever while on holiday and developed a high concentration of antibodies against the virus. A sero-epidemiological prospective study then showed conclusively that EBV was indeed the cause of the disease.

So much for history. What do we know about the virus? Does it really contribute to Burkitt's lymphoma — and nasopharyngeal cancer — as is claimed? Is there any point in developing a vaccine against EBV to prevent these diseases? Why else should EBV be the subject of so much and such intense research?

EBV is a typical herpesvirus, the exemplar of the  $\gamma$ -herpesvirinae. It contains 170 kb of double-stranded DNA, encoding something like 100 proteins, and its genome structure is known in great detail<sup>3</sup>. It is noteworthy for its complexity and remarkable examples of long range splicing. The large number of proteins it encodes seems to be related to its need to cope with many types of cellular metabolism — it grows in B cells and epithelial

## Mummy deterioration halted by nitrogen atmosphere

MANY museum objects are damaged by microorganisms and insects (see A. David *et al. Science in Egyptology*; Manchester University Press, 1986). We have developed a method to control biological damage and to provide optimum display conditions, and have used a 3,000-year-old Egyptian mummy as a model (see figure). This woman was 40 years old when she died and came from a rich family, shown by the mummification treatment and by a layer of gold over her eyes. The mummy was placed in a hermetically sealed display case and the air replaced by nitrogen at low relative humidity. The combination of low relative humidity (35-40 per cent) and oxygen level (less than 2 per cent) significantly decreases

the biological activity (95 per cent) of microorganisms isolated from the mummy, assessed using carbon-14 tracers. A sealed display case with controlled humidity and a nitrogen atmosphere was designed at the Getty Conservation Institute by Frank Preusser. This is a prototype for showcases to be used in the Egyptian Museum in Cairo. By contrast with common fumigation systems, nitrogen is safe, inexpensive and easily handled. In art object preservation, a nitrogen atmosphere could be an effective means for drying and disinfecting water-damaged materials, and for eliminating insects from museum collections.

Nieves Valentin

Nieves Valentin is visiting the Getty Conservation Institute, Marina del Rey, California 90292, USA, and is at the Instituto de Conservación y Restauración de Bienes Culturales, Madrid, Spain.

cells and can undergo a latent or lytic infection. Since the number of its potential hosts is small (humans and a few primates), its characteristic property of persistence for long periods of time in a latent stage from which it can be rapidly activated is sensible behaviour.

The virus is very common, more than 90 per cent of the world's population is infected. It is ironic that a suggestion of a viral involvement in a not very common cancer, of limited geographical distribution, should have led to the discovery of one of the commonest human viruses. The most interesting property of EBV is that both *in vitro* and *in vivo* it infects and immortalizes human B lymphocytes which then grow indefinitely. (The symptoms of glandular fever represent the cellular immune response to immortalized B cells.) It is the investigation of this property, and the gene regulation that governs latent immortalization and reactivation, that is the basis of EBV research today.

On the face of it, the infection of B cells clearly underlies Burkitt's lymphoma, which is a B-cell tumour, although the malignant transformed lymphoma cells are in many ways distinct from *in vitro* immortalized B cells. The tumour is clonal both for the cells and for the viral genome, so the virus was probably present in the original B cell that underwent malignant transformation. This seems compelling evidence for a causal malignant transformation between virus and tumour. The argument is strongest if few normal B cells are infected in those who develop the tumour. If, as is generally the case, the proportion is less than 1 per cent, the evidence is very strong indeed. It is not known, however, whether the percentage is so low in African children. Although EBV is almost certainly a contributory cause of Burkitt's lymphoma in the high-incidence areas of Africa it certainly is not a sufficient one (EBV-negative cases of Burkitt's occur all over the world). The effects of malaria on the immune system seem to be an essential factor — the true explanation of Burkitt's original observation of a climatic relation — and the tumour cells also possess a translocation which deregulates expression of the proto-oncogene *myc*. The translocation of *myc* is probably the transforming event. The role of immune surveillance is underlined by recent reports of true EBV-positive Burkitt's lymphoma in AIDS patients in the United States.

As a medical problem, Burkitt's lymphoma is hardly comparable with nasopharyngeal cancer, a disease which is most important in South-East Asia, with an incidence of 10–20 cases per 100,000

population a year. All tumour cells seem to contain virus, but the same reservations hold because nearly everyone has EBV in parts of their oropharynx. It seems that other factors must also be involved, for example, diet.

Following their original support for Epstein in the early 1960s, the CRC continued to support him in his pursuit of an anti-EBV vaccine as well as supporting much other EBV research. Vaccine research has concentrated on the glycoprotein antigen gp340 found on the viral envelope. The next step is to discover whether this molecule will evoke an immune response in man.

From a medical point of view, taking a

shot at producing a vaccine and going to field trials must be the priority for an organization whose *raison d'être* is cancer control. However, the significance of EBV goes far beyond this. It is a particularly valuable and interesting system in which to study virus latency and reactivation, exactly how the virus immortalizes the B cells, and it may shed light on more general aspects of cellular gene expression. Next week's conference should, with luck, bring us closer to understanding these questions. □

John Galloway is head of public relations at the Cancer Research Campaign, 2 Carlton House Terrace, London SW1 5AR, UK.

## QUANTUM ELECTRONICS

# Interference rules the waves

Gerhard Fasol

QUANTUM mechanics shows that electrons are waves. On the other hand, to explain conventional transistors, electrons are treated as classical particles propagating by diffusion. Thus there is usually no need to take the quantum-mechanical nature of electrons into account in modelling conventional devices. However, the wave character of electrons is unambiguously demonstrated by various experiments including tunnelling through potential barriers, which would be impenetrable for particles governed by classical physics, interference and diffraction. It is only recently that electron interference phenomena have become important in solid-state physics. Thus proposals for transistors based on quantum interference, as exemplified by an ingenious new design by F. Sols *et al.*<sup>1</sup>, are stimulating much interest.

In principle, transistors based on quantum interference are very attractive propositions, because of their very high expected speed. Thus they would be candidates for use in ultrafast computers, high-capacity telephone exchanges or satellite communication systems, for example. Unfortunately, present-day technology restricts such applications to extremely low temperatures (below 1 K). Thus conventional liquid helium cooling is not sufficient — a 'dilution' refrigerator is also needed. A common driving force of research on new types of transistors is to look for operating principles which use phenomena other than diffusion and charge-density modulation, which are both inherently slow. Deformations of wavefunctions and wave interference, on the other hand, are very much faster phenomena.

Maybe the most fundamental demonstration of the wave character of electrons is the generation of electron interference patterns, or electron holograms<sup>2</sup>. Electron

holography has recently been investigated very thoroughly by Akira Tonomura *et al.*<sup>3</sup> at the Hitachi Central Research Laboratory. Their experiment is based on the same principle as optical interference: an electron beam is split into two parts; the two partial waves then follow different paths and are subsequently allowed to interfere. The interference pattern is a consequence of the different phase of the two partial waves. In this way, magnetic flux patterns in superconductors or other structures which change the phase of an electron wave can be investigated.

Interference is well known for light waves: Newton's rings or the holograms used as a security device on credit cards are some well-known examples. A crucial condition for the observation interference phenomena is that the two beams interfering are coherent. This means that there must be a constant phase relationship between the two interfering partial waves over a time span corresponding to the difference in the path length of the two beams. In solids, it is not clear initially whether electron interference phenomena should ever be active, or indeed whether

The novel transistor proposed by Sols *et al.*<sup>1</sup> relies on interference between electron waves passing directly between drain and source and those diffracted via the stub. Applying a voltage to the gate changes the effective length of the stub, so that the waves can be made to interfere constructively (as shown) or destructively.

1. Epstein, M. A., Achong, B. G. & Barr, Y. M. *Lancet* **1**, 702–703 (1964).
2. Epstein, M. A., in *Burkitt's Lymphoma: a Human Cancer Model* (IARC Scient. Publ. No. 60 (1985)).
3. Farrell, P. J. *Adv. Viral Onc.* **8**, 103–131 (1989).

experiments can be constructed where they should be observable. This is because in an ordinary semiconductor or metal, electrons collide continually with lattice vibrations, impurities, dislocations and other lattice imperfections. In addition, electrons collide with each other. Thus under normal conditions the coherence length is expected to be much too short to observe any interference phenomena.

But recently it has become clear that elastic scattering (impurity scattering, for example) changes the phase of an electron wave in a reproducible manner. Thus the observation of electron interference is limited only by inelastic electron-electron scattering and by phonon (lattice-vibration) scattering, which can be reduced by cooling the sample to extremely low temperature. The phase coherence length for electrons in GaAs heterojunctions is of the order of 5  $\mu\text{m}$  at 0.1 K, decreasing rapidly as temperature increases (ref. 4; also D. Wharam, personal communication). Thus, using current knowledge, any possible device based on quantum interference of electrons would have to be operated at extremely low temperatures and using dimensions at the limit of today's technology. Nevertheless, solid-state physics has been a source of exciting surprises recently: the discoveries of the quantum Hall effects (see my earlier News and Views article<sup>5</sup>), or high-temperature superconductivity, both rewarded by Nobel Prizes, were not at all expected before their experimental discovery. Therefore we should not have any prejudices in this presently very exciting field.

Transistors (core components occurring millions of times in any electronic equipment) are three terminal devices. In one particular class of transistors there is a current entering at one terminal and leaving at another. A third terminal controls this current: a large change in current through the first two terminals occurs if a small voltage (or a small current) at the third terminal is varied. In an intriguing new suggestion for a quantum interference transistor<sup>1</sup>, F. Sols *et al.* propose to use the wave character of electrons for transistor action. The authors investigate theoretically the propagation of electron waves through a T-junction-type waveguide, where a stub of variable effective size is attached to an electron channel. Model calculations show that the transmission coefficient through the channel depends strongly on the size of the stub (see figure). The effective size of the stub can be varied by changing the voltage applied to a gate on the stub. Thus such a device can be used as a transistor.

Tunnelling is another manifestation of the wave character of electrons: currents can pass through thin regions of material classically forbidden to them. M.A. Reed *et al.*<sup>6</sup> have just demonstrated the operation of a 'quantum resonant tunnelling transistor' in which the strength of the tunneling current between two terminals can be modulated strongly by a voltage applied to a third terminal. The essential physics of the effect was recently described in News and Views by Luryi<sup>7</sup>.

Other suggestions of unconventional transistor principles include that by Sakaki<sup>8</sup>, in which the wavefunction of electrons is switched between high and low mobility states — a velocity-modulation transistor. In this device, applying a voltage distorts the wavefunction of the electrons in a layered transistor structure perpendicular to the plane in which electrons are confined. Thus the electrons can be deformed towards the Coulomb scattering centres, reducing their mobility; or they can be pushed away from the scattering centres, increasing their mobility. Such a transistor works by controlling the velocity of electrons. This is expected to be inherently faster than the usual modulation of the charge density.

Another proposal relies on the diffraction of electron waves from surface gratings<sup>9</sup>. In this device electrons are confined to a two-dimensional channel and exposed to a periodic modulation of the thickness of the well or of a potential. For a modulation of the period  $a$ , electrons with wavelength  $\lambda = a/z$  (or close to it) will be reflected off the periodic grating. This effect is analogous to the Bragg reflection of light waves or X-rays. Thus the speed of electrons of a particular kinetic-energy range will be strongly affected by the grating. 'Negative differential resistance' can be achieved — a phenomenon whereby the current decreases with applied voltage in certain ranges. In a transistor structure, an applied voltage would change the depth of modulation and thus the velocity of the electron waves. □

## PLANETARY ATMOSPHERES

# Impacts giveth and impacts taketh away

William B. McKinnon

COMETS have often been called upon to deliver life-giving volatiles and organic matter, early in the history of the Solar System, to the presumably barren surfaces of the terrestrial planets. Now, new research by Melosh and Vickery, on page 487 in this issue<sup>1</sup>, makes explicit the disquieting notion that bombardment by comets and asteroids can also erode, or even completely strip off, an atmosphere. The authors show by a simple model that Mars, with its relatively low gravity, is particularly susceptible. Working back in time, they find that Mars may have had an atmosphere with a surface pressure more like that of Earth at present. This idea has great scientific appeal as many lines of evidence point to a more clement Mars 3.8 thousand million or more years ago.

The idea that impacts can remove mass from an atmosphere is not new<sup>2</sup>, it is simply not well developed<sup>3,4</sup>. Melosh and Vickery have modelled the process numerically, but find that its essentials can be described by a simple analytical scheme. The specific mechanism they study is the interaction of the vapour cloud, produced when the impactor strikes the planetary surface, with the atmosphere. Other mechanisms have been studied, such as the shock waves produced by atmospheric passage and the entrainment of air by

high-speed solid ejecta<sup>3,4</sup>. In both cases, though, workers agree that the amount of atmosphere ejected is not more than a few times the amount intercepted by the projectile on the way in, or by the ejecta on the way out. The beauty of the vapour-cloud model is that much of the impactor's kinetic energy is transformed into vaporized impactor and target. The expanding cloud can then do work on the entire atmosphere in its line of sight.

Two criteria must be met for the expanding vapour cloud to blast the entire atmosphere in its sight to infinity. First, the impact must be fast enough for the vapour to expand at a speed greater than the planet's escape velocity, taking into account the considerable energy required for vaporization. Second, that the vapour mass must exceed the atmospheric mass in question. This is essentially a simple momentum balance. The characteristic sizes of rock impactors that can remove the entire air mass above a plane tangent to the surface are then roughly 3, 13 and 70 kilometres in diameter for Mars, Earth and Venus, respectively. Given these numbers, it is apparent that the atmospheres of all these worlds have been stable against impact erosion over most of geological time. That is, the number of impacts of this size are not great over a

Schematic diagram of the principal sources and sinks for  $\text{CO}_2$  in the early history of Mars.

few thousand million years at current cratering rates. The situation was entirely different during the first 500 million years or so of the Solar System, when the impact flux was orders of magnitude higher.

During the era of heavy bombardment, the authors show that the characteristic time for the martian atmosphere to be completely stripped is under 100 million years. Complete stripping is at least theoretically possible, because as the mass of the atmosphere declines, more numerous (and frequent) smaller impactors can erode it. Turning the problem around, Melosh and Vickery integrate backwards in time, undoing the effects of impact erosion. Using the agreed bombardment history for the inner Solar System (see the News and Views article by G. R. Stewart<sup>5</sup>), they show that Mars should have had a relatively thick atmosphere early in its history, barring other significant additions and subtractions. The atmosphere may even have been sufficient to allow running water on the planet's surface.

Impact erosion is clearly an important process in early planetary atmosphere evolution. The challenge ahead is to fit it into the general context. Atmospheres are, after all, not static entities. Earth's oxygen and nitrogen are maintained by living organisms. On Mars the situation is not as clear, but much research has focused on plausible histories for martian  $\text{CO}_2$ . The figure illustrates most of the important sources and sinks for  $\text{CO}_2$  on early Mars. Outgassing from the mantle is considered to be the ultimate source as the atmosphere is secondary, and is not derived directly from the solar nebula<sup>6</sup>. Comparison with the  $\text{CO}_2$  and carbonate budgets of the Earth and Venus suggests that Mars could easily derive an atmosphere with a pressure of many bars from this source.

Keeping it is another matter. Weathering of surface rocks and carbonate formation are estimated to cause the atmosphere to collapse on a timescale of  $10^7$

years according to Pollack *et al.*<sup>7</sup>. These authors invoke volcanic recycling to continually reflux  $\text{CO}_2$  back into the atmosphere. Mars was very active volcanically in early times, but as this activity waned, the atmosphere more-or-less irreversibly recombined with the surface. It may have halted only when the surface pressure reached the triple point of water (about 6 millibar), below which water will not stably exist, even transiently, and carbonate formation would cease<sup>8</sup>. Ground-based spectroscopic detection of the carbonate-bearing mineral scapolite in martian dust and soil has been reported recently<sup>9</sup>. (It is interesting to note that without life, Earth's atmosphere would also recombine with surface rocks, possibly leaving our planet in a Mars-like state, with only a thin, cold atmosphere of argon and  $\text{CO}_2$ .)

Impacts could have several effects on the early atmosphere (see figure). One is impact erosion. Impactors could also be a source of atmosphere if they are moving slowly enough. This is fine for asteroids, but Melosh states that comets generally move so fast that the vapour plume produced cannot be retained on Mars or the Earth (personal communication). Thus the idea that the Earth owes its oceans to cometary bombardment long ago may have to be abandoned. Impacts on Mars could also exhume and release carbonates. Schultz notes that erosion was much more intense on Mars before the formation of the last great impact basin, Argyre, than after<sup>10</sup>.

Perhaps the collapse of the martian atmosphere (recombination with the surface) was more tied to the impact history of Mars than to its volcanic history. Whatever the controlling factors, impact erosion is expected to occur, and may solve some old mysteries. Mars is depleted in argon compared to Earth and Venus, and this has been used to argue that Mars was less efficiently outgassed. Preferential impact erosion of the martian atmosphere may make this unnecessary<sup>1</sup>. Mars may be as efficiently outgassed as Earth, and thus may have released to its surface as much or more water per gram as Earth. □

## Spinning in space

THE traditional space rocket ejects a stream of hot combustion gases. This is almost the only way of generating the huge but short-lived thrust needed to lift a spacecraft away from the Earth's surface. But once in space, a satellite or probe could be just as well manoeuvred by a very small thrust applied for a very long time. One possibility is to exploit solar or nuclear power to accelerate a continuous exhaust stream of electrons and heavy ions. But Daedalus has another suggestion. His new rocket motor doesn't eject any kind of gas or plasma. Instead it fires out a *solid* exhaust.

His ingenious propulsion system melts-spins a glass or polymeric material into a transparent fibre, writes alternate positive and negative charges on it from electron and ion sources, and then accelerates it to high velocity in an electrostatic linear motor. No net charge accumulates on the spacecraft, as the ejected fibre is on average electrically neutral. And in the microgravity and hard vacuum of space, it could be drawn to extremes of small diameter, high tenacity and high final velocity. Daedalus calculates that a 0.5-micrometre fibre ejected from a spacecraft at 4 km per second would generate about 10 millinewtons of continuous thrust from a few watts of power, easily drawn from solar panels. Over the months of a long space mission, this could build up a useful velocity increment, or make possible delicate manoeuvring, for a tolerable loss of mass. And as a final brilliant stroke, Daedalus will use the ejected fibre as an optical communication channel to link the spacecraft back to Earth.

The 'Space Spider' poses some intriguing problems. DREADCO's mathematicians are already wrestling with the gravitational dynamics of the ejected fibre, so as to establish trajectories for the Spider which will not stretch or break its ever-extending fibre. This would certainly break at the Earth end if any attempt were made to lead it down through the atmosphere. It will have to be anchored to a command satellite, orbiting in a plane normal to the Spider's trajectory: this would waggle the fibre but would not stretch or entangle it.

One serious snag is that few optical fibres are usefully transparent over more than 100 km or so. So Daedalus, cunningly, plans to equip his space fibre with distributed optical gain. DREADCO's chemists are devising super-radiant glasses which will lase in the sunlight of space. An optical pulse passing down such a glass fibre will be continuously amplified, and will travel unattenuated for any distance.

The Space Spider will open up whole new strategies of secure-communication deep-space probes. Sadly, only one or two can be flying at any one time, or they will surely get tangled up. David Jones

# Regulation of kinase activity

**SIR**—In a recent News and Views article, Hardie<sup>1</sup> described the emerging evidence that protein kinases can be inhibited by interacting with substrate-like sequences. These sequences are present either within the same molecule, as in kinase C, or in a different molecule, as in the regulatory subunits of cyclic AMP-dependent kinases. I would like to point out that an inhibitory role of amino-terminal sequences over the carboxy-terminal catalytic domain has also been shown for p60<sup>v-src</sup>, a member of the non-receptor family of tyrosine kinases<sup>2</sup>. The mechanism whereby this negative regulation occurs has not yet been addressed, although studies performed on p60<sup>c-src</sup>, the cellular (c) homologue of the viral (v) protein, support the idea of substrate-like sequences being involved.

Amino-acid positions 90 and 92 of p60<sup>c-src</sup> are tyrosine residues, one of which is surrounded by acidic amino acids as are many tyrosine-kinase target sequences (see figure). These sequences are located in the amino-terminal regulatory domain of the molecule within a stretch of about 50 amino acids that are conserved among all the members of the *src* family. This region has been called the SH3 or A box<sup>3</sup> and it is not present in the receptor class of tyrosine kinases.

Activated p60<sup>c-src</sup> molecules, such as those bound to middle-T antigen of polyomavirus, or those present in certain neuroblastoma cell lines, are phosphorylated on tyrosine at their amino termini<sup>4,5</sup>. Based on their neighbouring sequences, tyrosine residues 90 and 92 represent the most likely targets of phosphorylation within this amino-terminal region. An

interpretation of these results is that in the off state the catalytic carboxy-terminal domain interacts with the amino-terminal substrate-like sequences. Phosphorylation of the amino-terminal site would only occur when the kinase is activated, presumably by an induced conformational change. Phosphorylation at these sites may allow maintenance of the on state.

A similar effect is observed with certain amino-acid substitutions of p60<sup>c-src</sup>. These are Gly 63→Asp, Arg 95→Trp, and Thr 96→Ile, which are present in the viral protein p60<sup>v-src</sup>, and are sufficient to increase the specific activity of the kinase<sup>6</sup>. The recombinant chimaeras between v-*src* and c-*src* used in these studies<sup>7</sup> are shown schematically in the figure. Among these three mutations, the crucial one is likely to be Arg 95→Trp, because Gly 63→Asp when present alone in p60<sup>c-src</sup> is silent, and Thr 96→Ile is not conserved in other strains of Rous sarcoma virus. Arg 95 is three residues away from the tyrosine-phosphorylation site and its presence could weaken the interaction with the kinase domain, thereby releasing the inhibition and allowing constitutive activation of the kinase.

A more rigorous proof that Arg 95 lies within a kinase regulatory domain has been obtained by Potts *et al.*<sup>7</sup>, who find that the Arg 95→Trp mutation alone is sufficient to activate p60<sup>c-src</sup>. In addition, this group and also L. Fox, K. Frost and J.S. Brugge (personal communication), have shown that mutations at either tyrosines 90 or 92, or the deletion of amino acids 92–95, activate the transforming potential and the kinase activity of p60<sup>c-src</sup>. Thus, it is possible that an intramolecular

negative control of kinase activity among the *src* family resides within substrate-like sequences outside the catalytic domain.

## Tale of two serines

**SIR**—In a recent paper<sup>1</sup>, Brenner used the fact that serine is encoded by two non-linked codon types, UCN and AGY, in conjunction with his observation that within several enzyme families catalytic serine residues have different codon representations, to propose that these serines evolved convergently by single substitutions in cysteine or threonine codons (UGY and ACN, respectively), the latter being catalytic residues in ancestral enzymes of each class. This proposal, however, fails to account for the serine codon representations of two groups of proteins.

First, the chymotrypsin-like proteases from *Streptomyces griseus*, SGPA and SGPB (ref. 2): in these enzymes, the catalytic serine residues are encoded by AGU and UCC, respectively, but the 61 per cent identity of amino acids between SGPA and SGPB, and their similar sizes, make it highly improbable that they belong to two different phylogenetic lineages, as predicted by Brenner's hypothesis. Second, the viral replicative proteins containing the widespread nucleoside-5'-triphosphate (NTP)-binding motif (refs 3–5) Gly-X-X-X-Gly-Lys-Ser/Thr (GXXXXGK S/T) where X is any amino acid: as shown in the figure and table, the lineages of the GKS-containing proteins of picornavirus, comovirus and nepovirus derived from serine codon types are incompatible with the phylogeny arising from sequence comparisons (compare *a* and *b* in the figure). Moreover, the conspicuous absence in this family of a GKT-containing protein is at odds with Brenner's additional suggestion that, in the case of the NTP-binding motif, threonine might be an evolutionary intermediate between the two kinds of serine, rather than their predecessor. It seems to be the case, in the proteins of this family, that threonine is not acceptable in the NTP-binding motif and that evolutionary transitions between UCN and AGY

Amino acids 81 to 106 of p60<sup>c-src</sup>. W, substitution of Arg→Trp as in p60<sup>v-src</sup>; asterisks are above tyrosines 90 and 92, underlines, acidic amino acids surrounding the tyrosine-phosphorylation sites. Lower panel, schematic diagram of various *src* proteins from: Schmidt Ruppel subgroup A Rous sarcoma virus, New York strain (SRA-RSV-NY); San Francisco strain (SRA-RSV-SF); chimaeric viral and cellular *src* recombinant viruses (NY851 and NYHB5); a non-mutated cellular *src* recombinant virus (NY5H). Mutations 63, 95 and 96 are indicated; vertical lines show amino-acid substitutions in other regions of the viral protein as compared with the cellular *src* protein. The relative kinase activity was measured by *in vitro* phosphorylation of enolase as previously described<sup>5</sup>.

Phylogeny of putative NTPases of picornavirus, comovirus and nepovirus. *a*, Phylogenetic scheme derived from the data of the table according to Brenner's hypothesis; *b*, phylogenetic tree generated by comparison of amino-acid sequences of evolutionary conserved segments of putative NTPases using a rate-independent distance matrix method<sup>7,8</sup>. Only the branching order is shown; the branch lengths were chosen arbitrarily. The branching order of this tree is identical to that generated for viral RNA polymerases<sup>9</sup> and for capsid proteins<sup>10</sup>, and presumably reflects the phylogeny of viral genomes as a whole. Codon representations of serine in the GKS consensus are shown. Where, in a group of viruses, only one codon series is utilized, the branching order was not further specified.

codons occur without GKT intermediates.

In two other families of viral GKS/T-containing proteins serine is encoded almost exclusively by UCN, with AGY occurring only once (see table). Again, it is unreasonable to suppose that the potexvirus gene containing AGU originated from a separate line of descent. Both these families, however, include GKT-containing proteins seemingly making the evolution of differentially encoded serines through threonine intermediates a possi-

bility. Nevertheless, it seems that if this occurred then it did so only rarely.

Although our survey of serine codon usage in putative viral NTPases does not support Brenner's hypothesis, it exposes some intriguing variations in the evolutionary mechanisms of different phylogenetic lineages. At least two mechanisms may be invoked to explain how the UCN to AGY transition occurs without loss of serine at the enzyme active site. The first of these requires the simultaneous change of two adjacent bases. Given the high error rate of RNA replication<sup>6</sup>, this mechanism is more feasible for RNA viral genomes than for DNA genomes. An alternative mechanism involves the generation of a new serine codon next to the functionally important one (yielding a

GKSS sequence with the two serines encoded by codons of different series) followed by deletion of the original codon. This mechanism is equally feasible with DNA and RNA genomes and might operate wherever there is no strict constraint on the residue(s) next to the functional serine. Generally, understanding the evolutionary history of serine codons in catalytic centres of each enzyme class requires knowledge of its phylogeny derived from independent data.

Serine codon representations in the nucleotide-binding motif of positive strand RNA viruses

Family of viral 'NTPases'	Consensus sequence	Serine (threonine) codons
<b>Family I</b>		
Alphaviruses	GKS	UCN
Coronaviruses	GKS	UCC
Furoviruses	GKS	UCN
Hordeiviruses	GKS	UCA
Tobraviruses	GKS	UCG
Potexviruses		
WC1MV p147	GKS	UCU
p26	GKS	UCU
PVX p165	GKS	AGU
p26	GKS	UCC
Tricornaviruses	GKT	ACN
Tobamovirus	GKT	ACC
Tymovirus	GKT	ACA
<b>Family II</b>		
Enteroviruses	GKS	UCN
Rhinoviruses	GKS	UCN
Cardioviruses	GKS	UCN
Aphtoviruses (FMDV)	GKS	AGY
Hepatitis A virus (HAV)	GKS	AGY
Comovirus (CPMV)	GKS	AGU
Nepovirus (TBRV)	GKS	UCG
<b>Family III</b>		
Potyviruses	GKS	UCN
Flaviviruses	GKT	ACN
Pestiviruses	GKT	ACA

For sources of sequence data see refs 4, 11 and 12. N, any nucleotide; Y, pyrimidine. The grouping of viral proteins containing the NTP-binding motif is according to refs. 4 and 12. Potexviruses (as well as furoviruses and probably hordeiviruses) have two putative NTPases each<sup>4</sup>. Different species of enterovirus and rhinovirus, and different strains of foot and mouth disease virus (FMDV) and HAV have either C or U in the third position; hence, N or Y is indicated, respectively.

## Telomere formation in yeast

**SIR**—We recently demonstrated that during formation of new telomeres in the yeast *Saccharomyces cerevisiae*, telomeric sequences are often transferred between DNA termini<sup>1</sup>. We argued that the most reasonable explanation for this transfer is recombination between DNA termini. In a recent News and Views article<sup>2</sup>, however, Szostak suggested that the telomere resolution reaction<sup>3</sup> (the cleavage between two blocks of telomeric sequences that are oriented as a head-to-head inverted repeat<sup>3,4</sup>) can provide an alternative explanation for our data, a possibility that can be addressed definitively by DNA sequencing. It is not clear to us why this possibility was raised because we stated<sup>1</sup> that our unpublished sequence data support the interpretation presented in the article; that is, the orientation of the transferred repeats is the same as that of the test termini (S.-S. Wang and V.A.Z., in preparation).

Although the sequence data eliminated the resolution model as an explanation for the telomeric transfer, we did not discuss these data specifically in terms of this model<sup>1</sup>. The resolution reaction never provided a likely explanation for our results because it requires three events: (1) circularization of linear plasmids bear-

ing telomeric repeats at each end; (2) asymmetrical resolution of the circles thus formed; and (3) telomere formation on an end with the telomeric repeats in the 'wrong'<sup>1,4</sup> orientation. Not only have none of these processes been demonstrated in yeast, but even symmetrical resolution is inefficient (~1 per cent per cell division)<sup>4</sup> compared with the sequence transfer we observe.

Because the resolution reaction is excluded unequivocally by DNA sequence data, telomere-telomere recombination remains the only reasonable explanation for the transfer of telomeric sequences that we have observed. Whether or not yeast exploits telomere-telomere recombination in the replication or maintenance of telomeres remains to be determined.

# 1989 FASEB SUMMER

The Federation of American Societies for Experimental Biology presents Summer Research Conferences designed for experimental biologists' analysis of research of intense scientific interest. The conferences in Saxtons River, Vermont and in Copper Mountain, Colorado will be limited to 150 persons each week and will be by invitation upon application. A conference fee of \$340 covers one week's room, board and registration. For further information and an application form, see the February *FASEB Journal* or call Dr. Robert W. Krauss, (301) 530-7093.

## Saxtons River, Vermont

 **RENAL HEMODYNAMICS: INTEGRATIVE AND CELLULAR CONTROL MECHANISMS** June 11-16 Chairs: L. Gabriel Navar, Tulane University Medical School; Donald L. Marsh, University of Southern California. **Structure and Development.** W. Kriz, A. Evan, D. Abrahamson, D. Casellas, L. Barajas; **Cell Biology of the Renal Microvasculature.** D. Schlondorff, J. Kreisberg, M. Dunn, K. Kurokawa, J. Bonventre, A. Hassid, W. Schrier; **Responses of Vasculature to Extrinsic Perturbations.** W. Arendshorst, H. Kirchheim, G. Navar, A. Premen; **Assessment of Renal Microvascular Responses.** M. Steinhausen, R. Edwards, P. Carmines, D. Harder, J. Briggs; **Tubuloglomerular Feedback Mechanism Control.** J. Schnermann, D. Bell, E. Persson, B-E. Persson, J. Davis; **Control of Renal Vasculature by Angiotensin.** R. Blantz, L. Rosivall, J. Hall, B. Ballermann, B. Zimmerman; **Neural Control of Renal Vasculature.** G. DiBona, E. Johns, V. Kon, M. Wolgast, N. Moss; **Regional Control of Intrarenal Hemodynamics.** F. Knox, R. Roman, S-Y. Chou, M. Sjoquist, R. Jamison; **Mathematical Modelling.** D. Marsh, L. Moore, K. Aukland, N. Holstein-Rathlou.

 **CELLULAR AND MOLECULAR GENETICS** June 18-23 Chairs: Gretchen J. Darlington, Baylor College of Medicine; Inder Verma, The Salk Institute. **Transcription Factors.** M. Rosenfeld, K. Calame, R. Tjian; **Organization and Action of Receptor Proteins.** K. Yamamoto, M. Johnston, C. Wu, J. Thorner; **Gene Regulation by Cytokines.** G. Darlington, G. Wong, J. Massague, G. ## **The Juxtaglomerular Apparatus**

### **Structure and Function**

With a contribution on the pathology of the human JGA by R. Waldherr

1989. 129 Abbildungen. Approx. 320 pages. Hard cover DM 248,-. ISBN 3-540-17837-6

This first-of-a-kind monograph on the juxtaglomerular apparatus demonstrates the association between structure and function for renin secretion, not only within the juxtaglomerular region, but also in the region of the renal cortex beyond the JGA. The description of the pathology of the human JGA, with references to experimental findings should help to make this monograph also useful for clinicians.

J.-P. Camilleri, C. L. Berry, J.-N. Fiessinger, J. Bari ty (Eds.)

## **Diseases of the Arterial Wall**

1989. 333 figures. Approx. 700 pages. Hard cover DM 650,-. ISBN 3-540-17492-3

This text combines extensive coverage of normal structure and function of the arterial wall with detailed accounts of the changes that occur in disease. Development and the factors controlling vessel form and structure are first discussed; then the normal cellular populations, functions and interactions are considered. Particular topics, such as pulmonary hypertension, the effects of trauma on vessels, and diabetic vascular disease are reviewed in detail.

G. Schettler, Heidelberg (Ed.)

## **Recent Results of Research on Arteriosclerosis**

Ver ffentlichungen aus der Geomedizinischen Forschungsstelle der Heidelberger Akademie der Wissenschaften

1988. 4 figures. VIII, 34 pages. (Sitzungsberichte der Heidelberger Akademie der Wissenschaften, Jahrgang 1988, Supplement 4). Soft cover DM 24,-. ISBN 3-540-50288-2

**Contents:** The Eberbach/Wiesloch Study: Influence of Cigarette Smoking on Lipoprotein Profiles. - Fish Oil and Occlusive Vascular Disease.

## **Advances in Anatomy, Embryology and Cell Biology**

Series Editors: F. Beck, W. Hild, W. Kriz, R. Ortmann, J. E. Pauly, T. H. Schiebler

Volume 116

H. Mizoguti, Kobe University School of Medicine

## **A Fifteen-somite Human Embryo**

1989. 57 figures. Approx. 85 pages. Soft cover DM 160,-. ISBN 3-540-50565-2

This book provides detailed morphological features of a very well-preserved human embryo with fifteen somites. The clear presentation in this book of embryonic development is increasingly important and highly relevant for in vitro fertilization, and thus of interest to reproductive biologists as well as anatomists.

Volume 115

S. Peel, University of Southampton

## **Granulated Metrial Gland Cells**

1989. 45 figures. Approx. 120 pages. Soft cover DM 120,-. ISBN 3-540-50390-0

The existence of Granulated Metrial Gland (GMG) cells in the uterus of many rodents during pregnancy has been known for decades. The recent discovery that bone marrow cells migrate to the uterus and differentiate into GMG cells during pregnancy is reviewed extensively for the first time in this book.

Volume 114

A. M. Dvorak, Boston

## **Human Mast Cells**

1989. 89 figures. Approx. 95 pages. Soft cover DM 140,-. ISBN 3-540-50374-9

This book provides criteria for the identification of human mast cells, discusses the unique role in mast cell function of granules and lipid bodies, describes the ultrastructural anatomy of two release reactions - i.e., anaphylactic degranulation and piecemeal degranulation - and defines the recovery, cyclical and maturational properties of human mast cells.

Prices are subject to change without notice.

B. Lachmann, University of Rotterdam (Ed.)

## **Surfactant Replacement Therapy**

in Neonatal and Adult Respiratory Distress Syndrome

1988. 130 figures. XXII, 372 pages. Hard cover DM 136,-. ISBN 3-540-18734-0

This book presents state-of-the-art information from the groups who have developed and used different types of surfactant. The latest advances concerning in vivo and in vitro evaluation of different types of surfactant as well as clinical consequences, such as changes in ventilator settings following surfactant replacement therapy and immunological questions, are discussed.

T. M. Schroeder-Kurth, University of Heidelberg; A. D. Auerbach, The Rockefeller University; G. Obe, University of Essen (Eds.)

## **Fanconi Anemia, Clinical, Cytogenetic and Experimental Aspects**

1989. 70 figures. Approx. 290 pages. Hard cover DM 138,-. ISBN 3-540-50401-X

This monograph represents the first attempt to gather all aspects of Fanconi's anemia in one source. The difficulties in differential diagnosis and treatment are covered; and the outlook for cure via bone marrow transplantation is included. This overview will interest specialists in human genetics as well as those dealing with this disease.

G. Valenti, Parma (Ed.)

## **Psychoneuroendocrinology of Aging**

**Basic and Clinical Aspects**

1989. Approx. 175 pages. (FIDIA Research Series, Volume 16). Hard cover DM 74,-. ISBN 3-540-96943-8

This book summarizes reports delivered at a recent workshop at the University of Parma. In the first part, the psychoneuroendocrine pattern in the so-called normally aging brain is described. In the second part, the psychoneuroendocrine pattern is depicted for the most stressful expressions of pathological aging such as the Alzheimer type, multi-infarct dementia, Parkinson's disease, depression and memory impairments.

# Trials of a lifetime

Alex Comfort

**The Retardation of Aging and Disease by Dietary Restriction.** By Richard Weindruch and Roy L. Walford. *Charles C. Thomas, Springfield, Illinois: 1989. Pp. 436. \$69.75.*

ONE of the few things we know — and have known for half a century — about the ageing process in mammals is that it can be slowed by caloric restriction. McCay's original finding has been repeatedly challenged and repeatedly re-verified, not only in mammals, the organisms which really preoccupy experimental gerontologists, but also in fish, invertebrates and test organisms generally. The apparent slowing, moreover, is not just a reduction in the diseases of overnutrition. Rather it is a moving to the right of the curve of survival, and the curve seems to move all identifiable landmarks with it: one would confidently predict that pedestrians subject to dietary restriction (DR) would have a peak for road fatalities at a higher age than those who are non-restricted.

Weindruch and Walford have produced a comprehensive book on this entire question. It powerfully concentrates the mind, notably by making it impossible to avoid asking why more effort has not been concentrated on assessing this effect in human beings. The mode of action of DR remains obscure — there are cellular, programme delay, error accumulation, neuroendocrine and immunological hypotheses, and the literature and evidence for all of them is painstakingly reviewed here for the first time. What precisely happens to molecular, physiological and immunological parameters is reviewed in equal detail, a fairly massive undertaking in view of the large range of organisms and the desultory character of much of the research. The purpose of this overview is to prepare us to ask ourselves whether, on the evidence, DR should work in human beings, and, if so, why no concerted attempt is being made to test it.

One can think of a number of answers to the last part of the question — actuarial studies on diet are by nature a two-lifetime project unlikely to attract funding sources wedded to instant gratification; and non-actuarial biomarkers, as the Hiroshima project investigators found, are quite difficult to choose and evaluate. Finding volunteers for lifelong, or even five- to ten-year DR projects might be difficult if significant numbers were needed. The numbers, however, depend on the magnitude of the effect: if four out of six dedicated dieters, evading Makeham's coefficient, lived to >105–106 years of age, people might begin to take notice, though by that time other approaches to ageing control, by genetic manipulation, might have devalued DR as a clinical approach.

One can go on multiplying difficulties, and this, in fact, is what gerontologists have done so far. One must also suspect another and psychological factor, the fear of being thought overzealous in the style of the early rejuvenators. Weindruch and Walford, whose own research credentials are impeccable, confront the timid with reasoned argument and present here a research prospectus which is very difficult to fault or ignore. If we do not wilfully ignore it, we ought to be planning how to put it into effect rather than waste another 20 or so years arguing about it — landmark-

shifting has implications in developing a medicine of rate determination which goes considerably beyond the vulgar pursuit of mere longevity.

It is refreshing to come across a text that is not only readable and a comprehensive review of its subject, but also a challenge to researchers and funding bodies; we can either extend our control over the life cycle or prove the authors wrong by trial. Walford is a respected figure and the founder of gerontoimmunology who is known to carry out dietary trials on himself. Anyone who views that undertaking as eccentric should feel obliged to respond to the admirably presented case contained in this book. □

Alex Comfort, *The Windmill House, The Hill, Cranbrook, Kent TN7 3AH, UK, is Adjunct Professor at the Neuropsychiatric Institute, University of California at Los Angeles, and a former Head of the MRC Research Group on Ageing at University College London.*

## Down to Earth

Ian D. R. Mackinnon

**Meteorites and the Early Solar System.**

Edited by John F. Kerridge and Mildred Shapley Matthews. *University of Arizona Press: 1988. Pp. 1,269. \$55, £42.95.*

AT FIRST glance, the study of meteorites must appear to be an unusually obscure discipline, made more so by jargon and a confusion of terms. There have been successful introductory-level, undergraduate texts on the subject, but these have wisely glossed over the debates on interpretation of the meteoritic record. The detail required to do justice to such issues would hardly excite any publisher, and an aspiring author would risk losing tenure at the most tolerant of institutions. It has taken a unique combination to break the mould: an outstanding specialist publisher, and the patience and tenacity of two well-known members of the space-science community. Several excellent books, co-edited by Mildred Matthews, have appeared in the University of Arizona Press "Space Science" series; this most recent publication, co-edited with John Kerridge, maintains the standard.

In 1,200 pages, the editors and 68 collaborating authors make a stellar effort at providing a précis of early Solar System history interpreted through the meteoritic record. The broad sweep of meteorite studies, which cover many scientific disciplines and employ a multitude of techniques, is clearly evident in the tone and content of the volume. Moreover, it's not all petrography and isotopic signatures. Included are well-written summaries of current astrophysical models of pre-nebula and solar nebula evolution, as well as of

models of nebula accretion processes. In many of the contributions attempts have been made to relate models to the observational record and to present the pros and cons of contentious issues. Some of them, such as that linking asteroids and meteorites, are successful; others are less so, but as much because of gaps in the record than any lack of effort.

Although some may quibble with the precise positioning of chapters, or even with the emphasis on Solar System/nebula processes, there is no denying the success of the overall format. Telling questions to be asked of multi-authored volumes are how well concepts are related between different chapters, and whether authors who might not ordinarily be seen sipping tea together at the annual meeting of the minds have been persuaded to collaborate. Here it appears that contributors did bother to read drafts of other chapters, and have delivered the goods. In those chapters where unlikely collaborations have been imposed, good summaries of research have resulted and some have provided new insights which perhaps have surprised even the authors.

The book was in gestation for well over two years, and that time has been fruitfully used. Here we have a coherent and detailed overview of the dominant processes affecting chondrite meteorites, from early nebula formation (or survival?) of precursor grains, to their accretion and incorporation in an asteroidal parent body, followed by various impact processes, ejection from dominantly asteroidal orbits, and then eventual collection and transfer to the laboratory for study. Most chapters specifically address chondrite meteorites only, as these are believed to have undergone the least degree of modification since their formation about  $4.5 \times 10^9$  yr ago. However,

helpful explanatory references to achondrites such as SNCs (purportedly derived from Mars) and ureilites are scattered throughout. One chapter on igneous activity, which at first blush would be a questionable entry, has been neatly integrated into the rest of the text. The relationship between the terrestrial planets and asteroids, as revealed by meteorite studies, is also well developed in a series of chapters under the heading "Chemistry of Chondrites".

A firm editorial hand is also evident in the highly consistent use of symbols, acronyms, abbreviations and units of measure. In addition, the glossary and useful compilations of fundamental data in five appendices will be appreciated by many readers. The index has received the same thorough treatment — entries under "Meteorites, individual" occupy almost two pages and give a quick synopsis of the chondrites whose characteristics have primarily shaped current thinking on processes of the early Solar System.

In early correspondence on the proposed book, Kerridge made two important conditions for the final product. First, he felt that it needed to be well balanced and cohesive. Second, that it was not to be a vehicle for perpetuating dogma; many meteoriticists need reminding of this point, as it is often all too easy to follow the gurus. No doubt because of that prompting, many authors have made genuine efforts to sketch the nub of controversies where they exist and, more importantly, to suggest means for their eventual resolution. The final chapter on future directions is a thoughtful assessment of meteorite studies and a rich source of ideas for research proposals in this, and related, fields.

Meteoritics has come a long way since the days of Harvey Nininger and Harold Urey, to whose memory this volume is dedicated. Both were in their sunset years during the halcyon days of the Apollo programme, which gave new life to the study of meteorites as well as to that of the Moon. Both played a large part in the development of meteorite research and they would, no doubt, be proud of this singular community achievement. □

Ian D. R. Mackinnon is Director of the Electron Microscope Centre, University of Queensland, St Lucia, Brisbane, Australia 4067.

• *Nature's* next review supplement, Spring Books, appears in the issue of 20 April. The books covered include *Digging into the Past*, Edwin Colbert's autobiography, *AIDS: The HIV Myth* by Jad Adams and *AIDS and Its Metaphors* by Susan Sontag, *Journey into Light*, a biography of C. V. Raman, *Does God Play Dice?* by Ian Stewart, Stuart Sutherland's dictionary of psychology, and two controversial works in archaeology. Among the reviewers are Jeremy Sabloff, Daniel S. Greenberg, Walter Gratz, Michael Berry, Roy Porter and Robert M. May.

## Learning of the Lucky Country

Robert A. Stafford

**Nature in Its Greatest Extent: Western Science in the Pacific.** Edited by Roy MacLeod and Philip F. Rehbock. *University of Hawaii Press: 1988. Pp.288. £27.20, \$34.*

**The Commonwealth of Science: ANZAAS and the Scientific Enterprise in Australasia, 1888–1988.** Edited by Roy MacLeod. *Oxford University Press: 1988. Pp.417. £25, \$45.*

THE motive proffered by Defoe's Captain Singleton for his peregrinations — "knowledge of things begat a desire of increasing it" — may serve as a simple explanation for the sustained European effort to penetrate, understand and organize the lands washed by the Pacific Ocean. Because Singleton was modelled on the circumnavigator Dampier, the analogy is particularly apposite, for Dampier's observations of natural phenomena created the vogue for South Seas exploration which endured throughout the eighteenth century and resulted in Britain's colonization of Australia.

With interest now turning to the Pacific basin as the theatre for the next major phase of economic development, it is appropriate that the historical role of Western science in the region should be assessed. Australia having celebrated its bicentenary, it is equally fitting that analysis of the place of science in the culture and economy of the island continent should be included in this analysis. The contributors to these two new books, which complement R. W. Home's *Australian Science in the Making* (Cambridge University Press, 1988), explore some of the more prominent features of what remains in many respects an intellectual *terra incognita*.

The function of the historian as pioneer is especially apparent in *Nature in Its Greatest Extent*. In conjunction with Philip Rehbock, Roy MacLeod has collected ten essays documenting European scientific activity in the Pacific from the eighteenth century to the present. The book opens many doors, revealing the wealth of materials that will enable future researchers to tell us in greater detail how Europe's discovery and exploitation of the lands of the Pacific transformed not only the region's peoples and habitats, but the mental landscape of Europeans. Individual contributions to the volume, however, are variable in quality, while the book as a whole is marred by incoherence of theme. The editors might have supplied a connecting overview in their introduction, but instead they pose questions

which the text fails to answer adequately.

The problem lies in defining the changing nature of the symbiotic relationship which has obtained between Western science and expansionism. Europeans were activated by greed as well as curiosity in coming to the Pacific. Science received patronage during the eras of exploration and settlement in exchange for the promise to deliver new resources for exploitation, new means of subduing hostile environments, effective methods for maintaining European ascendancy and cultural prestige for the metropolitan powers.

None of the essays covering the centuries before the Cold War sufficiently emphasizes that many European scientists were active agents of imperialism rather than mere fact-gatherers engaged in pushing back the frontier of the unknown. By means of their reports, maps, collections, taxonomic classifications and — more directly — their administrative and military duties, scientists facilitated the gradual imposition of European domination over the Pacific. As mediators of this new world, scientists played a large part in moulding European attitudes towards it. Their research agendas and results were, in turn, conditioned by European cultural norms, so that apparent objectivity often masked or reflected subjective metropolitan aspirations and anxieties. The same process was occurring in other regions which, as the editors fail to mention, presented challenges to Western intellectual assumptions and physical capabilities as daunting as those of the Pacific.

The book is divided into three sections. The first concentrates on the scientific content of the voyages of discovery and the tension between science and politics in their planning and execution. The second section, which offers more insightful analysis, examines how European science transplanted to the Australasian colonies sought to fulfil duties assigned by metropolitan savants while developing the impetus to assert its own authority and priorities. The long march of colonial scientists seeking intellectual independence was inexorably intertwined with the movement for political independence.

These essays likewise illustrate that science at the colonial periphery suffered severe constraints in comparison with that practised in Europe. Researchers were few on the ground, facilities rudimentary and funds scarce. Colonial culture often exhibited a philistine attitude towards the scientific enterprise, and the tyranny of distance between Port Moresby and Sydney was as real as that separating the South Pacific from London or Paris.

The final section moves into the twentieth century, when the winds of change which swept away the old empires cleared the ground for the new imperialism of the superpowers and the transnational corpo-

rations. In the interwar years, we learn, a burst of internationalism produced the Pacific Science Association, whose congresses have fostered an enduring tradition of cooperation among Pacific scientists. But following the Second World War, as many colonies discovered that political independence amounted to the perpetuation of subservience as client states of the United States or the Soviet Union, Pacific science traded old masters for new. The stars and stripes and the hammer and sickle now fly over far more scientific vessels or research stations than do the flags of other Pacific nations, or even the stubborn Tricolour.

As the last two chapters demonstrate, American and Soviet science remain as motivated by commercial and strategic concerns as were the scientific establishments which served the European powers during the exploration and colonization of the Pacific. But although the sciences have been employed for centuries as instruments of policy, scientists have with equal consistency shown themselves to be adept at exploiting governments to support research programmes that are ultimately driven by personal ambitions as well as disciplinary goals. It is in explicating the fine detail of this interplay that one of the most exciting frontiers of the history of science in its wider social dimension lies.

In *The Commonwealth of Science*, MacLeod embarks alone as editor to chart the history of science as it has developed in Australia during the twentieth century. On surer ground here than among the long Pacific swells, he builds upon the corpus of research published by the prolific Antipodean community of historians of science, as well as upon his earlier work on the British Association (the model for ANZAAS) and science policy throughout the empire. The story of ANZAAS, the Australian and New Zealand Association for the Advancement of Science, provides the prism through which we are invited to view science in the Antipodes from 1888 to the present. Coinciding with Australia's bicentenary, the ANZAAS centenary represents a convenient benchmark for surveying the evolving style and role of organized natural knowledge in the economic and cultural development of the nation.

The book contains several provocative essays, but again the quality is uneven. In two chapters discussing the foundation and early years of ANZAAS, MacLeod sets a standard of excellence — indeed, of eloquence — which some of his contributors fail to sustain. Institutional histories chronicling various disciplines alternate with analytical chapters which examine the meaning of science, the Australian national identity and man's place in nature. Rather than being a history of ANZAAS, the book provides an overview of the social role of science in Aus-

"The Pathfinder" — Science forging her way into the light (*Daily Telegraph*, 1911).

tralian history. This weakness is its strength, and in scope and penetration *The Commonwealth of Science* has a great deal to recommend it. We might wish, however, that MacLeod himself had completed the chronological narrative in the interests of keeping ANZAAS at the centre of things.

Nevertheless, we are left with an important contribution to the history of science in a former European colony and to the sociological literature on what it means to be Australian. Two recurring themes in the 15 chapters are the tensions between Antipodean colony and European metropolis, and between an imported culture and the alien environment upon which it has been imposed. Science figures squarely in these issues, for it has provided a venue for the articulation of Australian aspirations towards independence while simultaneously serving as a mediating device for the exploitation and understanding of a continent new to the European consciousness. Australia was born to the scientific age, so it is not surprising to learn that ANZAAS has functioned as a central reference point in the continuing adventure of creating an outpost of Western civilization in the South Pacific. It has proven a valuable public resource in a culture often branded as materialistic and anti-intellectual.

It remains to be seen whether Australia

will succeed in forging an effective national science policy. Such a strategy must harness the sciences to the goal of transforming Australia from the status of a supplier of primary products to that of a truly sovereign nation whose industrial and service sectors have attained critical mass and whose society has made the commitment to education and research-led change which is necessary for self-sustaining growth. As several contributors warn, the odds are at least even that Australians may fail, and that, as the Lucky Country devolves into a banana republic, the nation's tradition of scientific excellence will be dissipated like so many of her natural resources.

There are healthy signs, however, that this grim prognosis can and will be avoided by policy makers, and that Australia will maintain its reputation as the land of the second chance. The upsurge of interest in the role of science in the nation's history is one such encouraging sign, and these two books represent the cutting edge of the reappraisal. Anyone interested in the fate of Australian science, or indeed in the future of the country, should read *The Commonwealth of Science*. □

## Divisions in botany

Deborah Charlesworth

**Mutation, Developmental Selection, and Plant Evolution.** By Edward J. Klekowski, Jr. Columbia University Press: 1988. Pp. 373. \$55.

EDWARD Klekowski has made a brave attempt to put together all the available information about mutation in higher plants. His aim is to use the data to support the argument that genetic loads in plants are increased, in comparison to those in animals, by somatic mutation.

The germ cells of higher plants are differentiated anew each reproductive season from several separate meristems, rather than being sequestered in a permanent germ line as in multicellular animals. This means that the number of mitotic cell divisions between the zygote stage and meiosis in the germ cells, which in a plant are formed by a line of cell descent, may on average be much higher than in, say, *Drosophila* or a female mammal (although the number is, of course, higher in male mammals). If there is some probability of a somatic mutation arising at each cell division, the frequency of mutations among the gametes produced by a tree increases with the number of mitoses, which in plants is correlated with age.

Evidence for a correlation between the number of cell divisions before meiosis and rate of mutation has recently been provided by Miyata's analysis of the rates of evolution of sex-linked loci in mammals, which have many more divisions in the male germ line than in the female (*Cold Spr. Harb. Symp. Quant. Biol.* **LII**, 863–867; 1987). Thus the mutation rate per generation should be higher in a long-lived plant, such as a tree, than in shorter-lived species. An old tree, or an old clone of a fern species, would also be expected to be chimaeric, with different meristems of the same genetic individual carrying different and independently generated mutations. In the book, a mass of anatomical and developmental detail on meristems illustrates the various patterns that might occur.

Klekowski devotes most of his text to evidence for these ideas. Unfortunately, it is difficult to estimate mutation rates and to compare species with different life spans, and the few data on mutation in plants are mostly from short-lived species. Because a species with characteristics that tend to increase the mutation rate would probably experience selection to reduce it, such estimates might in any case not show the expected differences. Klekowski therefore discusses mutational processes

and error correction mechanisms in great detail, but as so little is known about these in plants it is difficult to make the necessary comparisons. The frequency of mutant gametes in plants of different age, and the existence of chimaeras, could also be tested, but here again the data are too limited to be of much use.

In the absence of direct tests of the hypothesis, Klekowski marshalls many pieces of circumstantial evidence that agree with his expectations. This necessarily yields a somewhat confusing picture, as such arguments can be wrong in at least two ways. First, some of the phenomena may not be due to genetic load; for example, although genetic load could be the cause of low numbers of seeds per

ovule in trees, other explanations such as selection for high pollen production in these plants, are also possible. Second, interpretations other than Klekowski's could explain differences between the genetic loads of populations. Differences in breeding systems, for example, are largely ignored in the book.

Klekowski therefore does not make a watertight argument for his hypothesis. But, although his book is hard to read because of the diversity of the information presented (a glossary would have helped), it is certainly interesting and rich in ideas for future research. □

## Vorsprung durch biotechnologie

Stephen Oliver

**Biotechnology Focus 1: Fundamentals, Applications, Information.** Edited by R.K. Finn and P. Präve. Hanser, Munich/Oxford University Press, New York: 1988. Pp. 436. DM128, \$85.

RIGHTLY or wrongly, English has become the international language of science. This is not to say that there is no need for scientific works to be written in other languages, but it does mean that translations into English must be viewed critically.

The American editor of *Biotechnology Focus* justifies the book's translation from German by asserting that in Europe, unlike the United States, genetic engineering has not excluded microbiology and chemical engineering from the area of biotechnology. I am sure there are those at, say, Madison or the Massachusetts Institute of Technology who would take issue with him. The other contention is that the book will unlock a literature unavailable to English-reading scientists. In fact, the principal biotechnologists in the German-speaking world habitually publish in English and less than 12 per cent of the references in *Biotechnology Focus* are to works in German. The longest chapter is on fungal pathogenicity, which is not an obviously biotechnological subject. This chapter is also one of those with the most German-language works in its bibliography; but it does not provide a ready entry to the German literature because only one of the 61 works (in all languages) quoted is actually referred to in the text. Clearly, editorial rigour has failed on one side of the Atlantic or the other, perhaps a case of passing the buck or *Verantwortung abschieben*.

*Biotechnology Focus* is described as a yearbook, but it is not in the mould of the

American Society of Microbiology's prestigious "Microbiology" series. Most of the contributions are of broad scope, such as the excellent chapter on scale-up theory by Hempel. This, however, sometimes makes them rather too general, as is the case with the contribution on computer control of antibiotic production. Sometimes a very general title disguises a very specific article — "Fundamental Methods of Genetics" mainly deals with the details of protoplast fusion technology using the hydrocarbon-metabolizing yeast, *Yarrowia lipolytica*. A great deal of experimental detail can be found in the book, for example in the account of cell immobilization. But this chapter appears in a section labelled "Applied Biotechnology", and so it is curious that the protocols described are for bench-scale work only. Overall, one has the impression that the editors did not have a clear idea of the book's purpose and so the authors have struggled manfully with an inadequate brief.

The topicality that might be expected of a yearbook is provided by an "Information" section. This is a good idea which is spoilt by the time-lag involved in translation — a company profile has Biogen still operating in Geneva, and the market values of bulk bioproducts are given in 1982 deutschmarks. The German-speaking world has made, and is making, an outstanding contribution to biotechnology; it is sad to see it so poorly represented. □

Stephen Oliver is a Professor in the Department of Biochemistry and Applied Molecular Biology, and Director of the Manchester Biotechnology Centre, UMIST, PO Box 88, Manchester M60 1QD, UK.

• Two books published late last year will be useful to researchers in biotechnology who have an eye on the potential commercial value of their work. *Protecting Biotechnology Inventions: A Guide for Scientists* is by Roman Saliwanchik and is published by Science Tech Publishers, Madison, Wisconsin (distributed outside North America by Springer-Verlag); *Patents: A Basic Guide to Patenting in Biotechnology* is by R. S. Crespi and is published by Cambridge University Press.

SAUNDERS SCIENTIFIC PUBLICATIONS

**ANNOUNCING**  
***A major new journal in  
the biological sciences***

*Editor-in-Chief*

Arthur S. Levine

National Institutes of Health  
Bethesda, MD USA

*European Editor*

David P. Lane

Imperial Cancer Research Fund  
Clare Hall Laboratories UK

*Associate Editors*

Don W. Cleveland—John Hopkins University School of Medicine, Baltimore

Raymond F. Gesteland—University of Utah Medical Center, Salt Lake City

Jeff W. Lichtman—Washington University School of Medicine, St. Louis

Roger M. Perlmutter—University of Washington, Seattle

Michael B. Yarmolinsky—National Cancer Institute, Bethesda

To encourage the development of unifying theories in cell and molecular biology, **THE NEW BIOLOGIST** is dedicated to the rapid publication of insightful reports on a diversity of biological systems and models.

These are a few of the topics that will be included in this new international journal:

- Eukaryotic and prokaryotic gene structure and expression
- DNA replication
- Signal transduction

- Molecular and cellular immunology
- Mechanisms of neurotransmission
- Plant and animal developmental regulation

In addition to original research reports, **THE NEW BIOLOGIST** will regularly feature:

- Meeting reviews that capture the major themes of conferences throughout the world;
- Reviews of new topics of wide interest - and of specialized topics of broader significance than previously perceived;
- Editorials from members of the biological research community.

**CALL FOR  
PAPERS**

Authors are invited to submit papers with new data of multidisciplinary interest. The journal will aim for rapid publication of accepted papers..

**THE NEW BIOLOGIST** will be published monthly beginning in October 1989. Manuscripts for this issue should be submitted by June 1, 1989. Authors in all parts of the world except Europe submit manuscripts to: **THE NEW BIOLOGIST**, 1666 Connecticut Avenue, N.W., Suite 300, Washington, D.C. 20009.

Authors in Europe submit manuscripts to: **THE NEW BIOLOGIST**, Saunders Scientific Publications, 110 Gloucester Avenue, Primrose Hill, London NW1 8JA, U.K.

For more information about the journal and manuscript submission, write to the Managing Editor, Ruth Kulstad; or call (202) 387-3934. For subscription information, write to: Saunders Scientific Publications, The Curtis Center, Independence Square West, Philadelphia, PA. 19106, Attention: Periodicals Marketing. Special subscription rates will be available for students.

Reader Service No.2

ANNOUNCING AN IMPORTANT EVENT IN SCIENCE PUBLISHING!

# THE MACMILLAN MOLECULAR BIOLOGY SERIES

General Editor: Dr C J Skidmore, University of Reading

MACMILLAN MOLECULAR BIOLOGY

## Genetic Elements in *Escherichia coli*

by Dr Peter Smith-Keary

Written for students of molecular genetics and molecular biology, the first volume in the series sets the scene by introducing aspects that provide the scientific background for the major technical advances of genetic engineering. Central topics such as replication, mapping, mutation, transposition and both general and site specific recombination are fully documented.

PB 0333 442687 £9.95 HC 0333 442679 £25.00

## Organelles

by Dr Mark Carroll

Aimed at second and third year undergraduate students following courses in biochemistry and cell biology, *Organelles* draws together the latest developments in our understanding of the ultrastructure and function of cell components. Each major cell organelle is the subject of one complete chapter, which ends with self-study questions to focus the reader on central concepts and principles. Throughout the book there are numerous micrographs and line illustrations.

PB 0333 44244X £9.95 HC 0333 442431 £25.00 (February 1989)

### Forthcoming titles include:

**What is a Gene?** by Dr C J Skidmore

**Protein Biosynthesis** by Dr R Jagus

**The Molecules of the Cytoskeleton** by Dr L Amos and Dr W B Amos

Code 355

## ORDER FORM

Paperback copies are available on inspection to lecturers in the UK where this may result in an adoption of 12 or more copies. If you would like an inspection copy please indicate in the space provided and return this form to: Inspection Copy Department, Macmillan Education, FREEPOST, Houndmills, Basingstoke, Hants RG21 2BR.

Please send me:

# Helium isotope ratios in circum-Pacific volcanic arcs

R. Poreda\* & H. Craig

Isotope Laboratory, Scripps Institution of Oceanography, University of California, San Diego, La Jolla, California 92093, USA

\* Present address: Department of Geological Sciences, University of Rochester, Rochester, New York 14627, USA

Volcanoes in the 'Ring of Fire' surrounding the Pacific Ocean are sited on tectonic arc segments marking the great subduction zones where oceanic crust returns to the mantle. Helium isotope ratios in volcanic gases along these arcs are close to those found in mid-ocean-ridge basalts, revealing the presence of primordial  $^3\text{He}$  released from the wedge of mantle material above the sinking plate. These results show that although the subduction of oceanic crust drives the arc volcanism, the subducted crust itself does not contribute a major fraction of the upwelling magma.

LAVAS associated with subduction, broadly termed arc volcanics, range in composition from basalt to dacite. Although a number of source regions and models have been suggested for the origin of arc magmas<sup>1-5</sup>, a unified model has been difficult

to construct because the isotopic and petrological signatures often require different source contributions. Craig *et al.*<sup>6</sup>, who measured  $^3\text{He}/^4\text{He}$  ratios in volcanic gases from Japan, the Marianas and Mt Lassen, showed that the dominant source of helium was the mantle wedge rather than subducted oceanic crust or sediment, both of which are rich in radiogenic  $^4\text{He}$ . We expand on that initial work to assess  $^3\text{He}/^4\text{He}$  ratios in all the North Pacific volcanic arc systems with respect to the role of the mantle wedge and the nature of the subducted crust in oceanic and continental arcs. Our most detailed study was in the Aleutian-Alaskan arc, a major feature erupting both tholeiitic and calc-alkaline lavas and grading from an oceanic arc on the west to a continental terrain in the east.

Helium isotope measurements were made on volcanic gases associated with recent arc volcanism. We sampled summit fumaroles whenever possible to minimize interaction of the gases with older crust enriched in radiogenic  $^4\text{He}$ . Helium in phenocrysts from recent subaerial or submarine lavas was analysed by crushing in vacuum<sup>7</sup>. Figure 1 shows the  $^3\text{He}/^4\text{He}$  ratios in the nine volcanic arc terrains studied: Table 1 lists these and other data for the individual volcanoes.

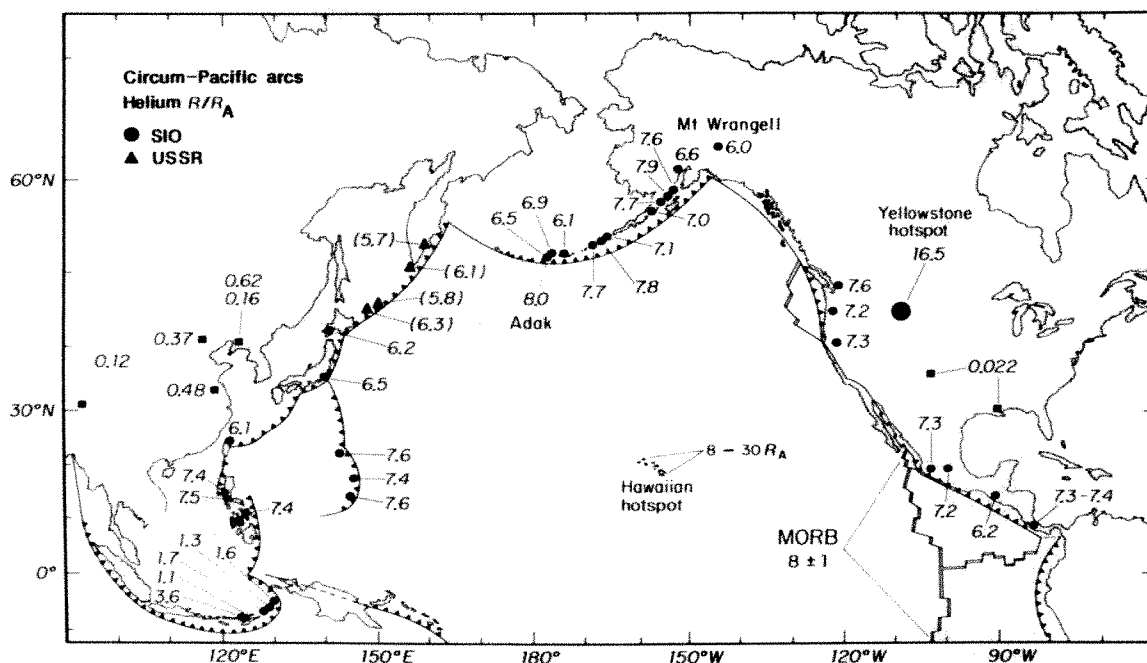

FIG. 1 Helium isotope ratios (relative to atmospheric He) in circum-Pacific volcanic gases and lavas, from this work (circles) and ref. 17 (triangles). A few data for the continental crust of China and the United States (squares) are shown for comparison, as are values for the Yellowstone and Hawaiian hotspots and for MORBs on the East Pacific Rise. Because radiogenic He has almost no  $^3\text{He}$  ( $R/R_A \approx 0.02$ ) the data show that the dominant source of helium in volcanic arcs is mantle (MORB) He with  $R/R_A = 8$ . Most arcs have He ratios from 7 to  $8 R_A$ , with a general mean of  $\sim 7.5 R_A$ , corresponding to  $X_M$ , the fraction of He derived from the mantle,  $\sim 7.5/8$ , that is, 94%. The Kurile-Honshu-Ryukyu arc system, including Japan, Taiwan, Kamchatka and the Kuriles, has a somewhat greater contribution of crustal or radiogenic

He, with a mean  $R \approx 6.4 R_A$  and  $X_M \approx 80\%$ . Similar values are found at Mts Spurr and Wrangell, volcanoes of the Aleutian-Alaskan arc system that are built on continental crust. The Banda arc, in the eastern sector of the Indonesian system, is caused by continental cratonic material (Australian plate) underthrusting oceanic crust. In this arc there is a much greater dilution of MORB He by the crustal component from the downgoing plate:  $R/R_A$  grades from 3.6 to  $\sim 1.4$ , proceeding eastward from the junction with the oceanic Sunda arc at Timor to the Banda Islands. The absolute flux of  $^3\text{He}$  from the mantle is known approximately<sup>25</sup>, so that volcanic arc fluxes of other volatiles can be derived from their ratios to  $^3\text{He}$  in arc lavas and gases.

### The Aleutian-Alaskan arc

Olivine phenocrysts from Mt Adagdak on Adak, and summit fumaroles on five volcanoes, Mts Okmok, Makushin, Griggs, Douglas and Augustine, have  $^3\text{He}/^4\text{He}$  ratios of  $R/R_A = 7.6$ – $8.0$  (where  $R_A$  is the  $^3\text{He}/^4\text{He}$  ratio in air), the highest volcanic arc values we have observed. These ratios are within the range for mid-ocean-ridge basalts ( $R/R_A = 8 \pm 1$ ; see, for example, refs 8 and 9) which agrees with the conclusion reached previously<sup>6</sup> that the mantle is the dominant source of helium in arc fluids. Along the entire length of this arc system from the Aleutian islands of Adak and Umnak, built on oceanic crust, to the Alaskan volcanoes Mt Douglas and Mt Augustine built on a

floor of Mesozoic sediments, there is no indication of any alteration in the  $^3\text{He}/^4\text{He}$  ratios from input of radiogenic  $^4\text{He}$ , even though trace-element and radiogenic isotope data show that sediments have contributed to these arc lavas<sup>4,10,11</sup>. At the eastern extremity of the arc, however, where the continental crust thickens and the trench-volcano gap abruptly widens<sup>12</sup>, the lower  $^3\text{He}/^4\text{He}$  ratios at Mts Spurr and Wrangell ( $6.6$  and  $6.0 R_A$ ) reflect significant contributions ( $\sim 20\%$ ) of crustal He from subducting terrigenous sediments<sup>12</sup> or the overriding continental plate.

Helium in volcanic gases consists of mantle He, radiogenic or 'crustal' He ( $R/R_A < 0.02$ ), and atmospheric He. The atmos-

The  $^3\text{He}/^4\text{He}$  measurements were made on a Clarke-type double-collecting mass spectrometer (GAD) as described previously<sup>7-9</sup>. In all cases helium was separated from neon on activated charcoal at 37 K to eliminate effects of variable He/Ne ratios on the measured  $^3\text{He}/^4\text{He}$  ratios of samples and standards. A secondary standard (Yellowstone Park gas:  $R/R_A = 16.45$ ,  $\text{He}/\text{Ne} > 1,000$ ) was used. Neon was also measured and the He/Ne ratios (column 5) were used to correct the measured  $^3\text{He}/^4\text{He}$  ratios, assuming all Ne to be atmospheric. Precision of the  $^3\text{He}/^4\text{He}$  ratios is 1%, unless otherwise stated. Total gas chemistry and  $^{13}\text{C}$  data will be reported elsewhere.

\* Sample key: SF, Summit fumarole; FF, flank fumarole; AS, acid spring; MP, mudpot; HS, hot spring; GS, gas seep; W, well; OL, olivine; CPX, pyroxene; F, fumarole. Data for OL and CPX examples include, at column 7, the He concentration in the phenocrysts, in  $10^{-9} \text{ cm}^3 \text{ STP g}^{-1}$ .

†  $R_C$  is the  $^3\text{He}/^4\text{He}$  ratio corrected for atmospheric He contamination<sup>10</sup>:  $R_C = (RN - R_A N_A)/(N - N_A)$ , where  $R$  is the  $^3\text{He}/^4\text{He}$  ratio,  $N = \text{He}/\text{Ne}$ , and  $A$  denotes the 'atmospheric' ratios.  $N_A$  is taken as the He/Ne ratio in air (0.288) for most fumaroles, or in water solution at 10 °C (0.230) for most hot-spring samples.

pheric component (obtained from the  $\text{He}/\text{Ne}$  ratio<sup>6</sup>) includes both entrained air in the natural feature and air added as a sampling artefact. The extensive data on Makushin volcano fumaroles show that the atmospheric and radiogenic components are correlated (see Table 1), indicating that the atmospheric component has for the most part been added in the crustal environment which contributed the radiogenic component.

### Western North America

Three volcanoes of the Cascades have  $^3\text{He}/^4\text{He}$  ratios of 7.2–7.6  $R_A$  in summit fumaroles and acid springs. Mts Baker, Hood and Lassen represent the northern, central and southern points

of the High Cascades respectively, but whereas the first two are andesitic volcanoes, Lassen is a dacite dome. Thus there is no evidence for a correlation of  $^3\text{He}/^4\text{He}$  ratios with the degree of magmatic differentiation in these volcanoes.

In the Trans-Mexican volcanic belt, two high-temperature geothermal systems, Los Azufres and La Primavera, have similar ratios,  $R = 7.3 R_A$ . Following the Middle American arc into Guatemala, the Zunil field associated with Santiaguito volcano<sup>13</sup> has fumaroles with distinctly lower values of  $R = 6.2 R_A$  that are boiling off from a deep chloride-rich water resident in older country rock, so that the  $^3\text{He}/^4\text{He}$  ratio is probably a lower limit. In Costa Rica, a summit fumarole on Poas volcano and

The  $\text{N}_2/\text{Ar}$  ratio can often be used to estimate the proper correction factor when the correction is important. When a range is shown for  $R_c$ , the upper and lower limits are calculated from the air and solubility correction factors respectively.

‡ NC, Non-condensable gases.

§ C. J. Nye (personal communication).

|| Re-analyses of original gas samples from Craig *et al.*<sup>6</sup> with Ne separation from samples and standards.  $R/R_A$  values are lower when Ne is removed from air standards: for example, the two Lassen Park analyses given here are 9% lower than the earlier values<sup>6</sup> measured without Ne removal.

¶ Submarine basalts dredged by Stern from Mariana arc seamounts: Eifuku at 21°45' N, 144°10' E, and Ruby at 15°12' N, 45°25' E on NSF-supported expedition: he also supplied the Sr isotope data.

\* J. C. Varekamp (personal communication).

borehole gases from the Marivalles geothermal field continue the consistency in  $^3\text{He}/^4\text{He}$  ratio ( $7.4 R_A$ ) for North American arc terrains.

### Western Pacific arcs

Helium isotope ratios in the central Western Pacific arcs, the Marianas and Philippines, are very similar to the North American values. In the Mariana arc a hot spring on Agrigan volcano<sup>6</sup> has a  $^3\text{He}/^4\text{He}$  ratio of  $7.4 R_A$ , and phenocrysts from two submarine volcanoes<sup>14</sup> have ratios of  $7.2$ – $7.65 R_A$ . Volcanic gases from the Philippine arc have similar He signatures:  $^3\text{He}/^4\text{He}$  ratios from Taal, Mt Pinatubo and Biliran Island range from  $7.4$  to  $7.5 R_A$ , identical to the Mariana and North American values. Lead isotope ratios in these volcanics also reflect a minimum contribution of subducted sediment<sup>15</sup>, although Sr isotope ratios are much higher than in western North American arcs<sup>16</sup>.

In the northwestern Pacific arcs, the Kurile–Honshu–Ryukyu system, a clear difference in the volcanic arc He signature is evident. In Japan, steam wells from the inner caldera of Hakone volcano have  $^3\text{He}/^4\text{He}$  ratios of  $6.5 R_A$ , and high-temperature ( $700^\circ\text{C}$ ) fumaroles on Usu volcano in Hokkaido have similar ratios of  $6.2 R_A$ . These Japanese ratios are distinctly lower than the Aleutian and North American values, but very similar to values in the Kuriles and Kamchatka<sup>17</sup>, shown in Fig. 1. Recent work<sup>18,19</sup> on Japanese hot-spring and volcanic gases shows a wide range in  $^3\text{He}/^4\text{He}$  ratios, converging in the high-ratio, high-He samples to a statistical distribution with a mean  $R/R_A = 6.5 \pm 1.5$ , uncorrelated with He or air content. It seems likely that this range of He ratios simply represents analytical scatter about a mean volcanic ratio,  $R/R_A = 6.5$ , which agrees well with both our earlier<sup>6</sup> and present data.

In northern Taiwan, gases from acid hot springs associated with Pleistocene volcanism in the Tatung region<sup>20</sup> range in  $^3\text{He}/^4\text{He}$  ratio from  $4.4$  to  $6.1 R_A$ . The Tatung field lies near the intersection of the Ryukyu and Luzon arcs,  $\sim 150$  km above the Benioff Zone defined by the subduction of the Philippine Plate beneath Eurasia<sup>21</sup>. Although the range in  $^3\text{He}/^4\text{He}$  ratios indicates the presence of a radiogenic  $^4\text{He}$  component, the highest ratio measured,  $6.1 R_A$ , is very consistent with the low  $^3\text{He}/^4\text{He}$  ratios in the Kurile and Japanese volcanoes.

### Indonesia

The most striking contrast to the relatively uniform  $^3\text{He}/^4\text{He}$  ratios observed in the other arc terrains ( $6$ – $8 R_A$ ) is the isotopic composition of He in the active volcanoes of the Banda arc in the eastern sector of Indonesia. The summit fumarole at Lewotolo, on the western edge of the Banda sector, has He with  $R/R_A = 3.6$ : eastward along this arc, three volcanoes have  $^3\text{He}/^4\text{He}$  ratios as low as  $R/R_A = 1.1$ – $1.6$ . Although it is possible that addition of  $^4\text{He}$  from circulating geothermal fluids is significant, it appears remote at Lewotolo and Damar ( $1.7 R_A$ ) with summit fumaroles at  $490^\circ\text{C}$  and  $170^\circ\text{C}$  respectively. In two cases, Serua and Sirung, the correction for atmospheric helium is large, but the corrected ratios also point to a helium source for all Banda arc volcanoes that is much more radiogenic than in any other arc gases so far analysed. The Banda arc lavas show extreme enrichments in Sr, Nd and O isotope ratios, all suggesting a major input of crustal material<sup>22–24</sup>.

### Discussion

The data here show that our previous observation<sup>6</sup> that active transport of mantle gases occurs in arc regimes is a general phenomenon in major volcanic arcs. In summit fumaroles uncontaminated by radiogenic  $^4\text{He}$  from older country rock, the  $^3\text{He}/^4\text{He}$  ratio is very close to that of mid-ocean-ridge basalts (MORBs) ( $R/R_A = 8$ ). Except for the Banda arc, the result of a unique arc–continent collision, the uniformity in  $^3\text{He}/^4\text{He}$  ratios contrasts markedly with the differences in tectonic setting and lava compositions of the arc systems. These range from the

continental arcs of western North America, where young crust is subducting into sediment-filled trenches, to the oceanic arcs of the Western Pacific, where old crust subducts into nearly sediment-free trenches. Andesites and dacites dominate the continental arcs whereas basalt and basaltic andesite are the major magma types in the oceanic arcs.

The arc helium signatures ( $R/R_A = 6$ – $8$ ) point to a MORB source dominating the production of arc lavas. Craig *et al.*<sup>6</sup> observed that if arc volcanics were simply remelted downgoing oceanic crust, then very low  $^3\text{He}/^4\text{He}$  ratios,  $\sim 2 R_A$  or less, would be observed because of radiogenic  $^4\text{He}$  production in old oceanic crust which should retain little if any primordial  $^3\text{He}$  (ref. 8). Hydrothermal circulation also removes large quantities of  $^3\text{He}$  from the oceanic crust. With a degassing rate of  $4 \text{ atoms cm}^{-2} \text{ s}^{-1}$  ( $1,000 \text{ mol yr}^{-1}$ ) of  $^3\text{He}$  (ref. 25) and a formation rate of  $3 \text{ km}^2 \text{ yr}^{-1}$  of oceanic crust, hydrothermal circulation will remove  $>10^{-5} \text{ cm}^3 \text{ s}^{-1}$  of helium to a depth of 5 km (ref. 8). Partitioning studies<sup>26</sup> show that  $<1\%$  of helium in a basalt lava resides in phenocrysts, so that cumulate gabbros do not hold  $^3\text{He}$ . Direct measurement<sup>27</sup> of 100-Myr-old basalt glass shows low  $^3\text{He}$  concentrations ( $0.5$ – $0.2 \times 10^{-12} \text{ cm}^3 \text{ g}^{-1}$ ) with ratios  $<3 R_A$ , because of radiogenic He production and diffusive losses<sup>9</sup>. These considerations all point to the conclusion that old oceanic crust is low in  $^3\text{He}$ , has a  $^3\text{He}/^4\text{He}$  ratio dominated by radiogenic  $^4\text{He}$ , and cannot be the major source of helium in arc lavas.

FIG. 2 A plot of  $^3\text{He}/^4\text{He}$  against  $^{87}\text{Sr}/^{86}\text{Sr}$  for 12 circum-Pacific arcs. The  $^3\text{He}/^4\text{He}$  data are from this paper, refs 17 and 50 (Kuriles), and ref. 36 (SIO data) and ref. 49 (New Zealand).  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios for lavas from the same volcano as the helium data were used whenever possible; error bars on Sr ratios reflect the range measured at a volcano. The curves are mixing trajectories between a MORB component ('M' =  $8 R_A$ ,  $0.7025$ ) and a crustal/sedimentary end member ('C' =  $0.2 R_A$ ,  $0.7080$ ) defined by a parameter  $\kappa = [(^{87}\text{Sr}/^{86}\text{Sr})_{\text{CRUST}} / (^{87}\text{Sr}/^{86}\text{Sr})_{\text{MORB}}]$ . Sedimentary  $^{87}\text{Sr}/^{86}\text{Sr}$  values are from refs 51 and 52. Note that whereas the  $^3\text{He}/^4\text{He}$  ratio of component 'C' is fixed at  $\sim 0$  (radiogenic He), the  $^{87}\text{Sr}/^{86}\text{Sr}$  will vary for different sources (for example,  $0.720$  for old Precambrian crust), so that the curves for  $\kappa$  values are pinned at the 'M' composition, but move left or right for 'C' components with smaller or larger  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios. Thus the  $\kappa$  values for mixtures depend directly on the Sr isotope ratio assumed for 'C'. The He/Sr ratio of MORB is reasonably well constrained within a factor of two ( $^4\text{He} \approx 10^{-5} \text{ cm}^3 \text{ g}^{-1}$ ,  $\text{Sr} \approx 120 \text{ p.p.m.}$ ,  $\text{He}/\text{Sr} \approx 3.2 \times 10^{-4}$  molar ratio). However, values of  $\kappa$  could vary by a factor of 100, from a minimum  $\kappa \approx 0.1$  for pelagic sediments with very low He retentivity, to  $\sim 0.2$  for old basaltic crust which lost all initial He at eruption, to  $\kappa \approx 10$  for Mesozoic and older continental crust ( $2.7 \text{ p.p.m. U}$ ,  $370 \text{ p.p.m. Sr}$ ). Thus an average 200-Myr-old crust which retained 50% of its radiogenic He might have a He/Sr ratio twice that of MORB.

Stern<sup>28</sup> discussed the similarities in  $^{87}\text{Sr}/^{86}\text{Sr}$ ,  $\text{K}/\text{Rb}$  and  $\text{K}/\text{Ba}$  ratios in primitive arc volcanics and oceanic island basalts and suggested that an enriched source region produces arc lavas. However, we note that *no arc terrain has a  $^3\text{He}/^4\text{He}$  ratio higher than that of normal mid-ocean-ridge basalt*. The  $^3\text{He}/^4\text{He}$  ratios of oceanic islands fall into two groups relative to MORB helium<sup>29</sup>: 'high- $^3\text{He}$ ' hotspots (for example Hawaii, Iceland, Samoa) have ratios significantly higher than MORBs<sup>9,29</sup> with  $R/R_A \approx 11$ –30, and could not be a source for arc magmas. However, the 'low- $^3\text{He}$ ' hotspots with  $R/R_A \approx 5$ –8 (for example, Jan Mayen, Azores or Gough<sup>30</sup>), do resemble arc magmas in their He signatures, and ratios of  $^3\text{He}/^4\text{He}$  in fumaroles and of  $^{87}\text{Sr}/^{86}\text{Sr}$  in lavas of the Aleutians and Cascades overlap the fields for Mohs Ridge and Azores Platform basalts<sup>31–34</sup>. As with other geochemical tracers the relationships between  $^3\text{He}/^4\text{He}$  and  $^{87}\text{Sr}/^{86}\text{Sr}$  do not provide a unique solution to the source for arc lavas, but it seems improbable that 'low- $^3\text{He}$ ' mantle source regions, principally found in the Atlantic Ocean<sup>29</sup>, should exist beneath every circum-Pacific volcanic arc.

The  $^3\text{He}/^4\text{He}$  and  $^{87}\text{Sr}/^{86}\text{Sr}$  distribution can also be produced by mixing a component from the subducting slab, rich in  $^{87}\text{Sr}$  and  $^4\text{He}$ , with a normal MORB mantle (He and Sr ratios of  $8.0$ – $8.5 R_A$  and  $0.7024$ – $0.7028$  respectively). Because of the similarity in  $^3\text{He}/^4\text{He}$  ratios between arc and MORB helium, it seems more probable that the source for arc volcanism resembles the MORB source in helium and that differences in  $^3\text{He}/^4\text{He}$  ratios and other geochemical tracers such as  $^{87}\text{Sr}/^{86}\text{Sr}$  result from a variable slab contribution from sediments or altered oceanic crusts.

### Helium–strontium relationships

Figure 2 shows the  $^3\text{He}/^4\text{He}$  data and measured or estimated  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios for lavas from the same sites (Table 1) on ten circum-Pacific arcs, with trajectories calculated for mixing a MORB component (M) with a possible crustal or sedimentary source (C). Most of the data are consistent with the addition of up to  $\sim 25\%$  of crustal He ( $R/R_A = 8$ – $6$ ), and up to  $\sim 65\%$  of the crustal Sr component, to a MORB source. That is, the values cluster in the region for  $\kappa < 1$  (see Fig. 2 legend), so that the fraction of mantle He in arc lavas is equal to or greater than the fraction of mantle Sr, consistent with a lower He/Sr ratio in the crustal component. The 'mixing curves' are of course subject to considerable uncertainties inherent in representing two very different elements such as He and Sr. Fumaroles on two andesitic volcanoes (Ngauruhoe,  $516^\circ\text{C}$ ; White Island,  $540^\circ\text{C}$ ) in New Zealand<sup>36</sup>, and two volcanoes (Pinatubo and Taal) on the West Philippine (Manila) arc, lie on the minimum  $\kappa$  curve ( $\kappa = 0.1$ ), suggestive of a MORB source diluted with a low He/Sr crustal component, possibly subducted pelagic sediment with a high  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio and Sr content.

Contamination of arc magmas during ascent through continental crust does not seem to have a large effect on  $^3\text{He}/^4\text{He}$  ratios. Because the U/Sr ratio is higher in crustal rocks than in MORB, pre-Cenozoic rocks that retain helium should have He/Sr ratios greater than MORB ( $\kappa > 1$ ) and on mixing with arc magmas should produce large changes in  $^3\text{He}/^4\text{He}$  ratios relative to  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios. In the Alaskan arc (Fig. 1)  $^3\text{He}/^4\text{He}$  ratios in the continental volcanoes of Mts Griggs, Douglas and Augustine are not lower than those of summit fumaroles in the Aleutian arc: indeed Mt Douglas ( $R = 7.9 R_A$ ) has the highest  $^3\text{He}/^4\text{He}$  ratio in the arc. Thus the influence of the Mesozoic continental crust on the  $^3\text{He}/^4\text{He}$  ratios of these magmas seems to be less than a 5% dilution. Sr isotope ratios support this conclusion, as no systematic gradient exists from the Aleutian to the Alaskan sectors<sup>32,35</sup>. However,  $^3\text{He}/^4\text{He}$  ratios for the two easternmost volcanoes in the chain, Mt Spurr ( $6.6 R_A$ ) and Mt Wrangell ( $6.1 R_A$ ), are significantly lower (Fig. 2, on the  $\kappa \approx 1$  mixing curve), very probably because of dilution with helium from a thicker continental crust.

The Banda arc data lie at the opposite extreme in Fig. 2, with

a crustal component amounting to  $\sim 80\%$  for He ( $R/R_A = 1.6$ ), and  $\sim 80$ – $90\%$  for Sr based on a  $0.7080$  end member. If, however, the  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio of the crustal end member is closer to  $0.720$  (refs 23, 24), as expected for the Precambrian Australian craton, the data would require  $\kappa \approx 5$  for a mixing curve, corresponding to a helium-rich crustal component. In fact the He/Sr ratio in Precambrian rocks is probably at least ten times the MORB ratio, and this end member would also fit the correlation between  $\delta^{18}\text{O}$  and  $^{87}\text{Sr}/^{86}\text{Sr}$ , which suggests a 25% sialic contribution<sup>23,24</sup>. Conversely, the Sunda arc lavas in the western Indonesian sector, with Sr ratios<sup>23</sup> of  $\sim 0.7048 \pm 0.0004$  derived from subduction of oceanic crust, are predicted (Fig. 2) to have  $^3\text{He}/^4\text{He}$  ratios of  $R/R_A = 7 \pm 0.5$ , with a well defined transition to the much lower Banda arc ratios near Lewotolo ( $R/R_A = 3.6$ ).

### Regional variations

Considering the  $^3\text{He}/^4\text{He}$  ratios in summit fumaroles, phenocrysts and least radiogenic samples, six volcanic arcs in Fig. 1 (the Aleutian–Alaskan arc, Cascades, Trans-Mexican belt and the Central American, Mariana and Philippine (east and west) arcs), have essentially indistinguishable mean ratios with  $R/R_A \approx 7.5 \pm 0.5$ , corresponding to a mantle He fraction  $X_M \approx 94 \pm 6\%$ . In the North Pacific only the Kurile–Honshu–Ryukyu arc system, including Kamchatka and the Kuriles, Japan and Taiwan, has clearly lower He ratios, with a mean value of  $R/R_A \approx 6.4$ , and a mantle He fraction of  $\sim 80\%$ . Although each of these arcs has a distinct geochemical signature which may reflect the composition of the mantle wedge or the age and composition of the overriding or subducting crust, no systematic correlation between these variables and the  $^3\text{He}/^4\text{He}$  ratios exists. Thus the Mariana arc, where the oldest oceanic crust (Jurassic) is subducting, has among the highest He ratios,  $R/R_A = 7.6$ , like the Philippine and Aleutian arcs where considerably younger crust is subducted. Most of the data points in Fig. 2 require a helium-poor component with a low He/Sr ratio ( $\kappa \approx 0.4$ ), either sediment or altered oceanic crust, mixing with a MORB source. Radiogenic production of  $^4\text{He}$  during 100 Myr with  $0.1$  p.p.m. of U should produce a He/Sr ratio of  $\sim 0.2$  times the MORB ratio if no He is removed, but because of the mobility of He and the lack of data on crustal He/Sr ratios, it is difficult to predict the nature of the 'C' component in individual cases.

Helium in arcs associated with subducting oceanic crust is almost entirely derived from a dominant MORB component in the mantle wedge, but we do not know at present whether the subducting crust is almost totally depleted of both  $^3\text{He}$  and  $^4\text{He}$ , or whether radiogenic He is still present in significant amounts but is not mobile. In the Banda arc of Indonesia most of the volcanic arc He (80%) is derived from subducting continental crust associated with a Precambrian craton, so that here at least a substantial increment of  $^4\text{He}$  relative to the He derived from the mantle wedge is retained during subduction and then mobilized into the erupting arc magma. Despite our uncertainties as to the processes actually responsible for cooking the final  $^3\text{He}/^4\text{He}$  recipes for arc volcanic gases and lavas,  $^3\text{He}$ , because it has essentially zero concentration in the oceanic and continental crust, is the most powerful tracer we have for studying the crustal contribution to arc magmas. □

ACKNOWLEDGEMENTS. We thank R. Motyka, J. Welhan, J. Varekamp, R. Poorter, S. Arnorsson, J.-L. Chemineau, F. Vidal, Y.-C. Chung, S. Matsuo and the late D. Johnston, who collected samples for us, often under hazardous conditions. R. Motyka provided logistical support to R.J.P. in the Aleutian and Y. Horibe worked with H.C. in the gas collections from Hakone and Usu volcanoes. We thank J. Urrutia and the INDE in Guatemala, F. Vidal and S. Mercado of the Instituto de Electricas in Mexico, and T. Powell of UNOCAL and P. Malixi and PNOG in the Philippines, for field assistance and logistical support. This research was supported by the Volcanology and Mantle Geochemistry Program of NSF.

# The *Drosophila* gene *torso* encodes a putative receptor tyrosine kinase

Frank Sprenger, Leslie M. Stevens & Christiane Nüsslein-Volhard

Max-Planck-Institut für Entwicklungsbiologie, Abteilung Genetik, Spemannstr. 35/III, D-7400 Tübingen, FRG

The maternal gene *torso*, required for determination of anterior and posterior terminal structures in the *Drosophila* embryo, was cloned using P-element tagging. Genetic evidence suggests that the action of the gene product is spatially restricted to the terminal regions; the *torso* messenger RNA, however, is evenly distributed. Structural similarities of the predicted *torso* protein with growth-factor receptor tyrosine kinases suggest that the spatial restriction of *torso* activity results from a localized activation of the *torso* protein at the anterior and posterior egg pole.

EARLY pattern formation in the *Drosophila* embryo depends upon maternal gene products provided during oogenesis and deposited in the freshly laid egg. For the determination of the anteroposterior axis of the embryo three classes of maternal genes have been identified: the anterior, the posterior and the terminal class<sup>1</sup>. Each class defines a pattern-forming process which results in the localization and/or activation of at least one maternal gene product which is necessary for the appropriate spatial expression of the zygotic target genes. In addition to the anterior and posterior genes, which function through localized components, a third organizing activity is required for the formation of the unsegmented terminal regions. At least six maternally expressed genes are necessary for the formation of the most anterior and posterior regions of the larva, acron and telson (as defined in ref. 1): *torso*(*tor*)<sup>2</sup>, *trunk*(*trk*)<sup>2</sup>, *torso*like(*tsl*) (H.-G. Frohnhofer, personal communication), *f(1)Nasrat* (*fs(1)N*)<sup>3</sup>, *fs(1)polehole* (*fs(1)ph*)<sup>4</sup> and *l(1)polehole* (*l(1)ph*)<sup>5</sup>. Embryos derived from mothers homozygous for mutations in this terminal class of genes fail to develop the labrum and the head skeleton is reduced in size. In addition, all elements posterior to the seventh abdominal segment are absent, including

the eighth abdominal segment and the telson. Mutations in any gene of the terminal class give an identical phenotype, which suggests that these genes are part of a single pattern-forming process that results in the spatially restricted expression or in the activation of zygotic terminal genes such as *tailless*(*tll*)<sup>6,7</sup>. In this pathway *torso* appears to play a crucial part, which is suggested by the phenotype of *torso* gain-of-function alleles. These mutations produce a phenotype opposite to the loss-of-function alleles<sup>7</sup>: elements of the termini are formed but the segmentation of the thorax and abdomen is suppressed. However, segmentation is restored in embryos which are in addition mutant for a null allele of *tll*. This indicates that the function of the *torso* product is mediated via *tll*, and suggests that in embryos of *torso* gain-of-function alleles, *tll* is expressed everywhere as a result of an ectopically active *torso* product. In the wild-type embryo the locally active *torso* product therefore provides cues required for correct spatial activity of terminal zygotic genes such as *tll*. Because cytoplasmic transplantation experiments revealed no localization of wild-type *torso* activity, it has been suggested<sup>7</sup> that the spatial restriction of *torso* activity may arise from a localized activation of the *torso* product through a modification mechanism by a preexisting spatial signal, which might be provided by one of the other terminal genes.

Here, we report that the product of the *torso* gene has structural similarities to receptor tyrosine kinases. This suggests a mechanism of the restricted *torso* action and provides a molecular explanation for the gain-of-function phenotype.

## Molecular cloning

The *torso* locus maps to the right arm of the second chromosome at cytogenetic position 43D3-E7. DNA from the *torso* locus was isolated by the P-element transposon tagging method<sup>8</sup> from *tor*<sup>TC17</sup>, a P allele obtained from T. Schüpbach. A genomic library was constructed from a subline of *tor*<sup>TC17</sup> in which many of the original P elements (over 50) had been removed by recombination. Two overlapping  $\lambda$  clones were isolated, which both contained 2.9 kilobases (kb) of P-element sequences and hybridized at cytological positions 43 E5-11 to wild-type salivary

FIG. 1 Structure of the genomic *torso* region. Numbers above the restriction map refer to distances in kb, the 0-point is defined by the P-insertion site. Mutations were mapped using Southern blot hybridization ( $tor^{XR1}$ ,  $tor^{XY83}$ ,  $tor^{QK25}$ ) and DNA sequencing ( $tor^{TC17}$ ).  $tor^{TC17}$  was isolated in a hybrid dysgenic cross (T. Schüpbach, personal communication),  $tor^{QK25}$  is an EMS-induced allele isolated by Schüpbach and Wieschaus<sup>2</sup>,  $tor^{XR1}$  is an X-ray-induced revertant of  $tor^{RL3}$  (ref. 7) and  $tor^{XY83}$  is an X-ray-induced revertant of  $tor^{Y9}$  (ref. 7). Embryos derived from mothers homozygous for these alleles develop a strong *torso* phenotype but show no other detectable phenotype. The filled bar represents the deleted region in  $tor^{XR1}$ , open bars above the triangles represent wild-type restriction fragments in which mutation-induced size changes were detected by Southern hybridizations. The 12-kb *EcoRI* fragment sufficient for P-element-mediated rescue is shown as a hatched bar. The two transcription units and their direction of transcription are presented as arrows. The exon-intron structure of the *torso* transcript, as inferred from the cDNA clone pCD7, is shown.

gland chromosomes. Fragments of these clones lacking P-element sequences were used to isolate  $\lambda$  clones from an Oregon P2 library, covering ~12 kb of DNA on either side of the P-insertion site (Fig. 1).

When the DNA structure of 35 ethyl methane sulphonate-induced and X-ray-induced alleles was analysed, three showed altered restriction maps in the cloned region as detected by Southern-blot hybridizations. The alleles  $tor^{QK25}$  and  $tor^{XY83}$  contain insertions of 5 kb and 0.5 kb, whereas the allele  $tor^{XR1}$  has a 9.5-kb deletion (Fig. 1) suggesting that this region contains sequences from the *torso* locus.

To confirm that we had cloned all of the sequences necessary for *torso* function, we used P-element-mediated germ-line transformation to rescue *torso* mutants. A 12-kb *EcoRI* fragment was cloned into the  $P^{PA}$  vector<sup>9</sup>, which carries the gene encoding alcohol dehydrogenase (*Adh*) as a marker and was injected into embryos from a strain mutant for both,  $tor(tor^{WK})$ , ref. 2), and *Adh* (*Adh*<sup>n2</sup>). Eleven independent transformant lines were obtained, all of which rescued both the ethanol sensitivity and wild-type *torso* function.

### The *torso* transcript

This 12-kb *EcoRI* fragment was used to screen a *D. melanogaster* embryonic complementary DNA library<sup>10</sup>. Two classes of cDNAs were isolated corresponding to two transcription units which are transcribed in opposite directions (TU1 and TU2) (see Fig. 1). Northern analysis revealed that the mRNA corresponding to TU2 is constitutively expressed during development (data not shown). Because only a portion of this transcription unit is contained within the rescuing *EcoRI* fragment, it is unlikely to represent the *torso* transcript.

Overlapping cDNA clones were isolated from TU1. The longest of these, pCD7 (3,063 base pairs (bp)), was used to examine the temporal expression pattern of the corresponding RNA on northern blots (Fig. 2a). A transcript of ~3.6 kb can be detected in RNA from 0–4-h-old embryos. After 4 h of development this signal is greatly reduced, but a very low level of expression is detectable throughout development after longer exposures. Adult females, but not males, show a high level of this transcript, consistent with expression in the ovary. In addition, a minor 5.5-kb transcript is visible after longer exposures (Fig. 2b). Neither the 3.6 nor the 5.5-kb transcript can be detected in RNA from the deficiency  $tor^{XR1}$  (Fig. 2b), indicating that both transcripts are derived from the *torso* region. Further analysis with smaller probes revealed that the 5.5-kb transcript is a 3'-extended version of the 3.6-kb transcript, suggesting that this minor transcript is the result of inefficient 3' processing of

the original transcript. Because TU1 has a pattern of expression that is consistent with a maternal gene, and because it is the only transcription unit entirely contained within the rescuing 12-kb fragment, we conclude that TU1 is the *torso* transcription unit.

### Expression of *torso*

The distribution of the *torso* transcript in ovaries and early embryos was examined by *in situ* hybridization to tissue sections. The transcript can be detected at low levels in the earliest stages of oogenesis (germarium, data not shown). It accumulates in the nurse cells until oogenic stage 10, with relatively low levels of transcript detectable in the oocyte (see Fig. 3a). After stage 11, when the nurse cells transport their contents into the oocyte very rapidly, the *torso* mRNA becomes evenly distributed within the oocyte and the nurse cells (data not shown). Immediately after egg deposition during early cleavage stages (Fig. 3b), the transcript is uniformly distributed in the embryo. During

FIG. 2 Northern blot analysis. a, Development profile of the *torso* transcript. For the developmental stages indicated, 20  $\mu$ g total RNA were analysed by northern blot hybridizations. Abbreviations: L: larval stages, P: pupae. For size calibration, an RNA-Ladder (BRL, Bethesda) was used. b, Over-exposure of a northern blot containing wild-type and  $tor^{XR1}$  total RNA. Each lane contains 20  $\mu$ g total RNA.

METHODS. RNA was run on 1% agarose gels containing formaldehyde and transferred to Hybond nylon filters (Amersham, UK). Hybridization was performed according to the manufacturer's instructions, using nick-translated pCD7 DNA as a probe. RNA isolation and other standard techniques were as described<sup>34</sup>.

syncytial blastoderm (Fig. 3c) the RNA moves towards the periphery of the embryo, apparently accompanying segregation of cytoplasm from yolk material. At the end of syncytial blastoderm, most of the *torso* RNA is found in the cytoplasm underneath the nuclei. The intensity of the label decreases with increasing age of the embryo and after cellularization no signal above background can be detected. The distribution of the *torso* transcript resembles that seen for total poly(A)<sup>+</sup> RNA<sup>11</sup> and shows no apparent localization. The observed signal is specific, however, because embryos and oocytes from homozygous *tor*<sup>XR1</sup> flies lack any signal above background levels (Fig. 3b).

### The *torso* gene and protein structure

We have sequenced both the 3.1-kb cDNA and approximately 4.7 kb of the genomic *torso* region (Fig. 4). The cDNA is truncated at both the 3' and 5' ends, but appears to contain the entire coding sequence (see below). The sequence ATCATTC, which fits the heptanucleotide consensus sequences ATCA(G/T)T(C/T) found at the 5' end of many *Drosophila* mRNAs (ref. 12), lies 105 bases 5' to the beginning of the cDNA sequence, suggesting that this may be the 5' end of the mRNA. In addition, a consensus TATA and CAAT-box (ref. 13) are 26 and 79-bp upstream from the presumed transcription start site. A consensus polyadenylation signal AATAAA, which is normally present some 10–30 residues upstream of the poly-A tail<sup>14</sup> directly follows the 3' end of the cDNA. The deduced length of the *torso* mRNA is therefore 3.2 kb, which is in good agreement with the 3.6 kb determined from gel migration and assuming a poly(A) tail of some 100 bases. Comparison of the cDNA and genomic sequences indicates that the *torso* gene contains at least 13 introns, which are, from 5' to 3', 67, 152, 60, 56, 68, 56, 57, 61, 67, 54, 60, 56 and 58 bp long.

Conceptual translation of the complete cDNA sequence in all three reading frames reveals a single long open reading frame of 2,936 bp that is preceded by an in-frame stop codon and

terminated with two stop codons. Within the first 82 codons after the stop codon which defines the start of the open reading frame there are three ATGs. Only the first exhibits a match to the consensus translation initiation site described for *Drosophila*<sup>15</sup>. Starting with the first Met, the open reading frame consists of 2,768 base pairs, encoding a 923 amino-acid (aa) protein with a predicted relative molecular mass of 105,162.

A hydropathy profile<sup>16</sup> of the predicted polypeptide (Fig. 5) displays a strongly hydrophobic region of 22 amino acids between residues 400 and 422. By the criteria of Klein *et al.*<sup>17</sup>, this hydrophobic segment has a high probability of spanning a membrane. This segment is preceded by a positively charged lysine residue that could interact with the polar groups of membrane lipids and is followed by two charged arginines that could serve as a transfer-stop signal. There are 15 potential glycosylation sites found in the sequence, twelve of which are amino-terminal to the hydrophobic segment. A shorter hydrophobic region of 17 amino acids is present at the amino terminus of the protein and exhibits several features typical for leader sequences which are important for transport into the endoplasmic reticulum (ref. 18). A possible cleavage site for the signal peptidase, deduced from the -3/-1 rule<sup>19</sup>, is between residues 20 and 21. These features of the primary structure suggest that the *torso* protein is a transmembrane protein consisting of an extracytoplasmic domain of 380 amino acids, a transmembrane domain of 22 amino acids and a cytoplasmic domain of 402 amino acids.

### A putative receptor tyrosine kinase

Comparison of the *torso* polypeptide with published sequences indicates significant homology between *torso* and proteins with tyrosine kinase domains. Alignment of the *torso* protein sequence with other protein tyrosine kinases reveals a high degree of amino-acid identity over the entire catalytic domain (Fig. 6), including the invariant lysine which is believed to be

FIG. 3 Spatial pattern of the *torso* transcript during oogenesis and early embryogenesis. *a* and *b*, Late stage-10 follicle. The nurse cell complex is to the left, the oocyte in the right half of the egg chamber. The dorsal side is up. No labelling can be detected in the follicle cells and the oocyte nucleus. *c* and *d*, Early cleavage (<2 h) wild-type (wt) and *tor*<sup>XR1</sup> (*tor*) embryo. *e* and *f*, Syncytial blastoderm embryo (<4 h). Most of the label is in the cytoplasm below the nuclei. No label was detected at any oogenic or embryogenic stage in sections from homozygous *tor*<sup>XR1</sup> females (only shown for early cleavage stage). Abbreviations: ocn: oocyte nucleus, nc: nurse cell nuclei, fc: follicle cell.

METHODS. Preparations of tissue sections and hybridization conditions using <sup>35</sup>S-labelled pCD1 derived antisense RNA were as described<sup>35</sup>. Embryos and ovaries were treated identically except devitellogenesis was omitted for ovaries. Oogenesis stages are those described by King<sup>36</sup>.

FIG. 4 Genomic and cDNA nucleotide sequence of the *torso* gene and the predicted *torso* protein sequence. The nucleotide sequence of the cDNA clone pCD7 is in upper case. Introns and genomic sequences not represented in the cDNA clone are in lower case. The predicted amino-acid sequence is shown below the nucleotide sequence, commencing at nucleotide (nt) 897. Amino-acid residues are numbered in italics. A putative CAAT (nt 518) and TATA box (nt 570), the conserved heptanucleotide at the presumptive transcription start site corresponding to the consensus ATCA(G/T)T(C/T) (ref. 12) (nt 597), the in-frame stop codons (nt 726, nt 4,537, nt 4,540) and the AATAAA polyadenylation signal (nt 4,636) are underlined. The putative transmembrane sequence is doubly underlined. Possible N-glycosylation sites<sup>37</sup> (consensus: N-X-(Ser/Thr)-X, with N as the glycosylation site and X any amino acid except Pro) in the amino-terminal half of the protein sequence are in bold face. The P-insertion site of the *tor*<sup>TC17</sup> mutation is between nt 944 and 945.

METHODS. Sequences were determined by dideoxy sequencing<sup>38</sup> using Sequenase (United States Biochemical Corporation) according to the manufacturer's instructions. Two strategies were used to prepare single-stranded DNA templates for sequencing. A genomic *Xba*I (nt 1411)–*Sac*I (nt 4283) fragment was randomly sheared by sonication and cloned into M13mp10. The rest of the genomic fragment and the cDNA was sequenced by cloning defined restriction fragments into M13mp18 or M13mp19 vectors. The complete sequence of both strands was determined for the genomic sequence. Three bases differ between the genomic sequence and the cDNA clone, probably as a result of reverse transcriptase errors during the construction of the cDNA library. In the cDNA, nt 707 is G, nt 2,320 is T and 2,568 is G. The resulting amino-acid change is Ile (405) to Val. We used the amino-acid sequence derived from the genomic sequence for further analysis. Sequence analysis was carried out using PCGENE software package (GENOFIT, Switzerland).

involved in the phosphotransfer reaction to tyrosine<sup>20</sup>. The homologies between the *torso* tyrosine kinase domain and the catalytic domain of other tyrosine kinases range from 42.4% for *ret* (ref. 21) to 29.9% for *eph* (ref. 22). This overall conservation between the *torso* peptide and tyrosine kinases derived from evolutionarily distant organisms such as mammals, strongly suggests that the *torso* protein functions as a protein kinase.

In addition to amino-acid identity within the tyrosine kinase domain, the *torso* sequence shares structural features with the subclass of receptor tyrosine kinases (RTKs). These molecules contain a relatively large extracellular domain, a single transmembrane domain, a juxtamembrane domain of 41–50 amino acids adjacent to the tyrosine kinase domain and a carboxy-terminal tail of variable length (reviewed in ref. 23). Because all these features are also present in the *torso* protein, it is tempting to speculate that *torso* encodes a receptor tyrosine kinase. As in three other RTKs, the platelet-derived growth-factor receptor (PDGF-R), macrophage growth factor receptor (CSF-1-R), and the putative receptor *c-kit*, which have been classified as type-III RTKs (ref. 23), the catalytic domain of the *torso* protein is interrupted by a stretch of hydrophilic amino acids. The class III RTKs are further characterized by an immunoglobulin-like structure in the extracellular domain which includes cysteines and conserved surrounding residues<sup>23</sup>. This immunoglobulin-like structure is absent in *torso* and comparison of the extracellular domains does not reveal similarities to other RTKs. Indeed, the amino-terminal half of the *torso* polypeptide shows no significant homology with any published sequence of the SWISS-PROT 6.0 and NBRF Protein 16.0 data-bases: *torso* therefore encodes a new type of receptor tyrosine kinase.

## Conclusions

The proposed structure of the *torso* protein and its similarity with growth factor RTKs suggest that the *torso* peptide is a transmembrane protein with an extracytoplasmic domain acting as a receptor and a cytoplasmic domain containing tyrosine kinase activity. RTKs are normally activated by the binding of a ligand to the extracytoplasmic receptor, resulting in the phosphorylation of specific proteins and eventually producing a pleiotropic response, including proliferation and differentiation<sup>24</sup>. We propose that *torso* participates in such a signal transduction mechanism, and that the generation of the signal and its subsequent transmission from the membrane-associated *torso* product to zygotic target genes are functions of the other terminal-class genes. Another example of a signal-transduction

process involved in pattern formation may occur in the developing eye of *Drosophila*; the product of the *sevenless* gene, which is required for the determination of the R7 photoreceptor cell has also been identified as a putative RTK (reviewed in ref. 25).

Although genetic evidence indicates that *torso* is normally activated only at the poles<sup>7</sup>, cytoplasmic transplantation studies<sup>7</sup> and the homogeneous distribution of the *torso* mRNA suggest that the *torso* product itself is not localized. Instead, the local activation of *torso* may be achieved through a spatially restricted ligand molecule. By analogy with other RTKs which reside in the cell membrane, the *torso* product is probably incorporated into the cytoplasmic membrane of the oocyte and early embryo. Its extracellular domain would then be in the perivitelline space, the region between the oocyte cytoplasmic membrane (oolemma) and the vitelline membrane surrounding the oocyte. If so, the *torso* protein could serve as a receptor for a ligand molecule which is present in a spatially restricted fashion in the perivitelline space. Such a ligand molecule could reach the perivitelline space by secretion either from the oocyte or from the somatic follicle cells which surround the oocyte during oogenesis. In this respect it is notable that there are specialized follicle cells at the anterior and posterior end of the follicle<sup>26</sup>, suggesting the possibility that a subpopulation of follicle cells may be responsible for producing the spatially restricted molecule necessary for the activation of *torso*. A potential candidate for encoding such a ligand is *torso-like*, which is distinct from the other *torso*-group genes in that it is dependent upon the somatic rather than the germ-line cells of the ovary (H.-G. Frohnhöfer, personal communication). A precedence for transfer of information from the somatic follicle cells to the oocyte is found in the establishment of the dorso-ventral axis in *Drosophila*. In this system, a mutation in the soma-dependent gene *torpedo* results in a ventralization of the embryo<sup>27</sup>.

The identification of *torso* as an RTK also suggests a molecular explanation for the *torso* gain-of-function phenotype. Because it is likely that the *torso* protein is present all along the anteroposterior axis of the embryo, mutations which cause the kinase activity to become independent of ligand binding could create an ectopically active *torso* product and thereby produce a gain-of-function phenotype. Consistent with this interpretation, mutations that result in constitutively active tyrosine kinases have been isolated in other RTKs<sup>23</sup>. The dorsal-group gene *Toll* also exhibits both gain- and loss-of-function alleles that produce opposing phenotype<sup>28</sup>, and like *torso*, *Toll* encodes a transmembrane protein<sup>29</sup> which is believed to be activated in a spatially restricted manner<sup>30</sup>. Although the biochemical activity of *Toll*

FIG. 5 Hydropathy analysis and structural organization of the predicted *torso* protein. *a*, Hydropathy analysis. The 923 amino-acid long *torso* protein sequence was scanned using the program of Kyte and Doolittle<sup>16</sup>. Hydrophobicity results in positive and hydrophilicity in negative values. *b*, Structural organization of *torso* protein. Landmarks in the sequence are indicated schematically: signal sequence (ss) and transmembrane domain (TM) are cross-hatched, the tyrosine kinase domains (according to Hanks<sup>39</sup>) are hatched.

FIG. 6 Comparison of the putative tyrosine kinase domain of the *torso* gene product with the corresponding domains of the products of the *ret* (ref. 21), human *c-src* (ref. 40), *Drosophila* EGF-receptor homologue (DER, ref. 41) and platelet-derived growth-factor receptor (PDGF-R; ref. 42) genes. Residues identical to the *torso* protein are in bold face and underlined. Classification into subdomains is according to Hanks *et al.*<sup>39</sup>. The lysine residue involved in the phosphotransfer reaction is marked by an arrow. Two sequence patterns which are thought<sup>43</sup> to distinguish all protein kinases from all other known proteins are marked with asterisks. The consensus pattern that specifies amino-acid specificity of the kinase to tyrosine residues, DLAARN, (in the catalytic domain VI) (ref. 39) is marked by #.

is not yet known, its similarities to *torso* support the hypothesis<sup>29</sup> that it functions as a receptor molecule.

The information generated by binding of the putative ligand molecule must ultimately be interpreted by the terminal zygotic genes. One maternally expressed gene which might be involved in carrying the signal downstream of *torso* is *l(1)polehole*. This gene has both maternal and zygotic functions and germ-line mosaic analysis<sup>5</sup> has shown that an embryo devoid of maternal *l(1)ph* mRNA but fertilized with a wild-type sperm develops a *torso* phenotype. The product of *l(1)ph* is likely to be identical to that of *l(1)raf* (refs. 31, 32), a homologue of the vertebrate serine/threonine kinase *Raf-1* (ref. 33). In addition, genetic evidence suggests that *l(1)ph* acts downstream of *torso* (M. Klingler, personal communication). Thus, signal transduction in the determination of terminal structure might involve a kinase cascade mechanism.

In summary, we propose that the *torso* gene encodes a receptor tyrosine kinase which is incorporated into the oolemma, but is not localized to the terminal regions. Its spatially restricted activity may be due to a local activation of the tyrosine kinase at the anterior and posterior ends of the embryo by binding of a localized ligand molecule to the extracellular domain of the *torso* protein. (In *torso* gain-of-function mutations, however, *torso* activity would be independent of ligand binding and the tyrosine kinase active everywhere.) Activation of *torso* would result in enhanced tyrosine phosphorylation of target proteins and the original signal would then be amplified by a cascade mechanism, in which at least one other kinase is involved. The activation of *torso* would ultimately lead to the regionalized expression of zygotic target genes, the next hierarchic level in the development of terminal structures of the *Drosophila* embryo. □

# Production of self-absorbed synchrotron spectra steeper than $\nu^{5/2}$

Martijn de Kool & Mitchell C. Begelman

Joint Institute for Laboratory Astrophysics, University of Colorado and National Institute of Standards and Technology, Boulder, Colorado 80309-0440, USA

**SELF-ABSORBED** synchrotron radiation produced by electrons with a power-law distribution of energies has a unique spectral shape: intensity  $I_\nu \propto \nu^{5/2}$  (where  $\nu$  is frequency), irrespective of the power law index of the electrons<sup>1</sup>. This well-known result has been applied recently to the 'far-infrared turnovers' observed in the spectra of many radio-quiet active galactic nuclei (AGNs)<sup>2-4</sup>. It has been asserted that the measurement of a spectral index greater than 5/2 at frequencies below the turnover is incompatible with the physics of self-absorbed synchrotron sources. Several observations suggesting larger indices (steeper slopes)<sup>5-7</sup> between the far-infrared and millimetre bands have been interpreted as evidence that emission by warm dust, not synchrotron radiation, dominates the far-infrared spectrum. Rees<sup>8</sup> has, however, pointed out that this assertion is not necessarily true. Here we show that plausible electron energy distributions can lead to self-absorbed synchrotron spectra which are steeper than  $\nu^{5/2}$  over 1-1.5 orders of magnitude in frequency. This indicates that none of the existing observations are in fact incompatible with self-absorbed synchrotron radiation as the source.

Consider an electron energy distribution consisting of the sum of two power laws,

$$N_\gamma d\gamma = C_1 \gamma^{-p_1} d\gamma + C_2 \gamma^{-p_2} d\gamma \quad (1)$$

where  $\gamma$  is the electron Lorentz factor and  $C_1$  and  $C_2$  are constants. Without loss of generality we shall assume in the following that  $p_1 > p_2$ . As  $\gamma > 1$ , this implies that the steeper power law can become of importance only if  $C_1 > C_2$ . The synchrotron intensity in the self-absorbed limit is given by the ratio of the emission coefficient to the absorption coefficient, which for  $p_1, p_2 > \frac{1}{3}$  reduces to

$$I_\nu = \frac{j_\nu}{\kappa_\nu} = \frac{C_1 j_1 \nu^{-(p_1-1)/2} + C_2 j_2 \nu^{-(p_2-1)/2}}{C_1 \kappa_1 \nu^{-(p_1+4)/2} + C_2 \kappa_2 \nu^{-(p_2+4)/2}} \quad (2)$$

where the analytic expressions for  $j$  and  $\kappa$  are well-known (see, for example, ref. 1). The coefficients  $j_1, \kappa_1$  and  $j_2, \kappa_2$  depend

on  $p_1$  and  $p_2$  respectively, and on the cyclotron frequency  $\nu_B$ . Equation (2) assumes the ultra-relativistic approximation for synchrotron emission. As the effects that we are considering are likely to be caused by relativistic electrons with  $\gamma \geq 10$  (see below), this approximation is justified. For simplicity, we also neglect effects of polarization and pitch-angle distribution. A proper treatment of these effects<sup>9</sup> yields results that differ from our estimate by less than a few per cent. Defining  $\eta \equiv C_2 j_2 / C_1 j_1$ ,  $\chi \equiv C_2 \kappa_2 / C_1 \kappa_1$  and  $q \equiv (p_1 - p_2)/2$ , we find that the slope of the spectrum is given by

$$\alpha \equiv \frac{d \log I_\nu}{d \log \nu} = \frac{5}{2} + \frac{q \nu^q (\eta - \chi)}{(1 + \eta \nu^q)(1 + \chi \nu^q)} \quad (3)$$

Evaluating  $\eta$  and  $\chi$  using the standard expressions for power-law synchrotron emission and absorption, it can easily be shown that  $\alpha > \frac{5}{2}$  for all  $\nu$ , although the deviation from  $\frac{5}{2}$  becomes arbitrarily small in the limits of both large and small  $\nu$ . Differentiating equation (3) with respect to  $\nu$  yields the value  $\nu_m$  at which the maximum slope  $\alpha_m$  occurs. The latter is given by

$$\alpha_m = \frac{5}{2} + \frac{q[(\eta/\chi)^{1/2} - (\chi/\eta)^{1/2}]}{[1 + (\eta/\chi)^{1/2}][1 + (\chi/\eta)^{1/2}]} \quad (4)$$

This maximum slope depends only on  $p_1$  and  $p_2$ . In Fig. 1 we show a contour plot of  $\alpha_m$  as a function of  $p_1$  and  $p_2$ , from which we see that a significant deviation from  $\frac{5}{2}$  occurs if  $p_1 - p_2 > 2$ . To illustrate the width of the interval in frequency that is affected by the steepening, Fig. 2 shows a contour plot of the spectral index  $\alpha$  in the  $(\nu, p_1)$  plane, for  $p_2 = 3$ . (The latter value is thought to apply in AGNs, in which an optically thin synchrotron spectrum proportional to  $\nu^{-1}$  is usually observed.) In Fig. 2 the frequency is normalized to  $\nu_m$ , so that the result is independent of the actual values of  $C_1$  and  $C_2$ . The spectral index is significantly steeper than  $\frac{5}{2}$  over 1-1.5 decades in frequency.

Our numerical experiments for arbitrary electron distributions indicate that the main feature of the electron distribution responsible for a spectrum steeper than  $\nu^{5/2}$  is

$$\frac{d^2 \log N_\gamma}{d \log^2 \gamma} > 0 \quad (5)$$

Although we cannot prove this condition rigorously, it can be understood by considering the case of two power laws. For a power-law electron distribution, a photon with a given frequency is on average absorbed by an electron with an energy lower than the average energy of an electron that emits at this frequency. (See, for example, ref. 1, equation [6.52].) This means that the

FIG. 1 Contour plot of the maximum spectral slope  $\alpha_m$  as a function of the power-law indices  $p_1$  and  $p_2$ .

FIG. 2 Contour plot of the spectral slope as a function of frequency and  $p_1$ , for a fixed value of  $p_2 = 3$ . The frequency is normalized to  $\nu_m$ , at which the maximum  $\alpha_m$  occurs.

FIG. 3 The spectral slope as a function of frequency for a self-absorbed synchrotron source containing a distribution of relativistic electrons that is a combination of a power law and a relativistic maxwellian (equation (6)). At low frequencies the spectrum is thermal ( $\alpha = 2$ ); it steepens considerably before becoming optically thin ( $\alpha = -1$ ) at high frequencies. The illustrated spectrum is for  $\beta = 1$  and  $C_1/C_2 = 1$ . The horizontal line represents a spectral slope of  $\frac{5}{2}$ .

absorption coefficient in equation (2) (the denominator) switches to being dominated by the first term (power law 1) at a higher frequency than the emission term (the numerator), so that the spectral index tends to  $\frac{5}{2} + q$  rather than  $\frac{5}{2}$ . Thus a distribution in which the number of low-energy electrons is over-represented relative to a power law extrapolation of the high-energy distribution is likely to produce a spectrum steeper than  $\nu^{5/2}$  over some frequency range. Note that neither the distribution function nor the derivative of its slope need be monotonic.

How can a relativistic electron distribution with the properties necessary for  $\alpha$  to be greater than  $\frac{5}{2}$  be produced in an AGN? A significant steepening of the electron distribution at low energies, relative to a power law, occurs if (1) there is extra injection of relativistic electrons at low energies described by a steep power law, for example from Fermi acceleration produced by many weak shocks; (2) there is a tail of a relativistic maxwellian distribution connecting with the power law at low energies, a situation that arises naturally if the effect of synchrotron self-absorption on the relativistic electron distribution is taken into account<sup>10,11</sup>; or (3) the net cooling rate of the relativistic electrons varies with energy in such a way that condition (5) is fulfilled. This would require that the cooling rate decrease towards lower energies more steeply than can be described by a single power law, or that there is a cooling mechanism that acts only in a restricted energy range.

The third possibility seems rather unlikely, but the first two are physically quite reasonable. Case (2), the combination of a relativistic maxwellian and a power law, is difficult to solve analytically, but we show in Fig. 3 our numerical results for the spectral index  $\alpha$  as a function of frequency, for  $N_\gamma$  of the form

$$N_\gamma = C_1 \gamma^2 e^{-\beta\gamma} + C_2 \gamma^{-3} \quad (6)$$

where  $\beta$  is an arbitrary constant. The strong inflection point in the electron distribution at the transition between the exponential tail and the power law causes a sharp peak in  $\alpha$ , with a width of about a decade. For  $\beta \approx 1$  and a wide range in  $C_1/C_2$ , the inflection point in the distribution (6), at which the two terms become equal, occurs for  $10 < \gamma < 50$ . If the usual order-of-magnitude estimate of the magnetic field strength in an AGN of  $10^3$  gauss is correct, this range in  $\gamma$  corresponds precisely to the range in energy containing the electrons responsible for the synchrotron radiation just below the turnover<sup>10</sup>.

Before comparing with observations, we must mention that there are effects that could flatten the observed spectrum from the ideal self-absorbed synchrotron spectrum we have discussed above. Prominent among these are radiative-transfer effects (if the source does not have a very sharp edge) or inhomogeneity (if parameters vary over the source surface).

The lower limits on the spectral slope below the turnover in observed AGN spectra are derived<sup>6</sup> mostly from the 100- $\mu\text{m}$  and 1.3-mm fluxes. To compare this with our results we have calculated the maximum average  $\alpha$  obtainable over such a factor-of-13 range in frequency. We find that this maximum is rather independent of the details of the model, and is about 2.75–2.8. The high value of  $\alpha$  of 3.06 reported<sup>7</sup> for wavelengths between 155 and 438  $\mu\text{m}$  in NGC4151 can also be reconciled with our models because, as Figs 2 and 3 indicate, steeper slopes can be obtained over a smaller range in frequency. These results imply that there are at present no measured spectral slopes below the turnover for which synchrotron radiation cannot be the main emission mechanism.  $\square$

## Anisotropic optical and X-ray emission in quasars

N. Jackson, I. W. A. Browne, D. W. Murphy & D. J. Saikia

Nuffield Radio Astronomy Laboratories, Jodrell Bank, Macclesfield, Cheshire SK11 9DL, UK

IT is of fundamental importance in the study of quasars to understand whether or not their continuum emission is isotropic, because this affects the overall energy budget and can also help to distinguish between the different models proposed for their central regions<sup>1</sup>. The reported small range of emission-line equivalent widths in quasars have earlier been used to argue against a relativistically beamed or anisotropic continuum<sup>2,3</sup>. Here we use recent spectroscopic observations of 46 radio-loud quasars to show that the equivalent width of the [O III] 5,007-Å emission line is strongly anticorrelated with the degree of radio core prominence  $R$ , which has been found to be a statistical indicator of orientation relative to the line of sight<sup>4–6</sup>. This observed anticorrelation shows that the quasar continuum is anisotropic and provides important evidence in favour of relativistic-beaming unified schemes<sup>4,7,8</sup>. We also show that the strength of the [O III] emission line is independent of  $R$ , consistent with unified schemes.

In relativistic beaming models, the radio emission from the core can be strongly Doppler boosted at small angles to the line of sight, because the material is believed to be moving relativistically<sup>8</sup>. On the other hand, the extended radio emission is at most mildly relativistic. Thus in such models the ratio  $R$  of core emission to extended radio emission is a useful indicator of source orientation, with  $R$  increasing as the angle to the line of sight decreases<sup>4</sup>. Several statistical studies have shown the radio properties of quasars to be consistent with such a scheme<sup>4,5,9,10</sup>.

A principal argument against extending such a scheme to include relativistic beaming of the optical and X-ray continuum<sup>11</sup> derives from the small range of emission-line equivalent width in quasars<sup>2,3</sup>. As the line luminosity should not depend on orientation, relativistic beaming of the continuum should be reflected in a spread in equivalent width, with the high- $R$  objects having systematically lower equivalent widths than low- $R$  objects.

To investigate this problem using a homogeneous set of spectra, we observed 46 radio-loud, low-redshift quasars with the Faint Object Spectrograph<sup>12</sup> on the Isaac Newton Telescope. Because we wished to study relativistic beaming of both the optical and X-ray continuum, most of the objects were selected on the grounds of having been studied at X-ray energies (2 keV) by the Einstein Observatory. Nearly all such objects with  $z \leq 0.8$  were observed, and several other quasars were added to fill gaps in the observing schedule, usually on the grounds of ease of observation and membership of the 3C catalogue. We emphasize that no prior selection by emission line strength has been imposed other than that implied by the necessity that all objects have measured redshifts and are classified as quasars by Véron and Véron<sup>13</sup>.

The spectral resolution of these observations is about 18 Å and the wavelength coverage is 5,000–9,500 Å. In every object, lines of H $\beta$  and [O III] 5,007-Å emission are observable. We have measured [O III] in all but three objects; for these three we have upper limits to [O III]. Full details of the observations,

calibration and data reduction are given elsewhere<sup>14</sup>. We have taken X-ray and radio luminosities from previous compilations<sup>11,15,16</sup>, supplemented in a few cases with radio data from our own unpublished Very Large Array (VLA) observations.

Here we focus on the [O III] line fluxes and their correlations with  $R$ , the ratio at 5 GHz of the core luminosity to the extended radio luminosity  $L_{\text{ext}}$  in the quasar's rest frame. We use [O III] because it is easier to measure than H $\beta$  and is less affected by contamination with broad Fe II blends<sup>14</sup>; moreover, it is emitted further from the quasar nucleus (a few hundreds of pc rather than a few pc) and orientation-dependent obscuration effects should interfere less with its flux.

In Fig. 1a and b we plot [O III] optical and X-ray equivalent widths against  $R$  (X-ray equivalent width is defined as the ratio of [O III] line flux to the K-corrected<sup>11</sup> X-ray continuum at 2 keV). The spread in equivalent widths is at least an order of magnitude and, contrary to earlier suggestions<sup>17</sup>, there is a very significant anticorrelation between the equivalent width and  $R$ . The formal levels of significance are listed in Table 1. If we accept relativistic beaming models, this result provides strong evidence that some part of the quasar continuum emission increases when viewed at small angles to the line of sight. We have examined the possibility that the above anticorrelation could be a secondary effect of a primary correlation between equivalent width and extended luminosity together with a selection-induced anticorrelation between extended radio luminosity and  $R$ . Both a partial correlation coefficient analysis<sup>18</sup> (Table 1) and comparisons of pairs of quasars matched in extended radio luminosity show that the equivalent width:  $R$  anticorrelation is significant. Moreover, in a virtually complete subsample (13 objects out of 17) from quasars having a flux at 2.7 GHz  $\geq 1.5$  Jy (ref. 19) and a redshift  $z \leq 0.8$  in the RA (right ascension) ranges over which we have data, the rank correlation is  $-0.74$ , giving a significance level of 99%. This suggests that selection effects are not responsible for the anticorrelation.

We can use our data to investigate whether the line and continuum luminosities lend independent support to the relativistic beaming unified scheme. If the low- $R$  and high- $R$  objects are intrinsically similar but differ only in orientation, their [O III] luminosities should be similar for a given extended radio luminosity. We indeed find that the hypothesis that the two distributions are indistinguishable cannot be rejected by a Kolmogorov-Smirnov test at the 80% level for 13 pairs of core- and lobe-dominated quasars matched in extended radio luminosity. Earlier studies have shown that, again for a given extended radio luminosity, the core-dominated (high- $R$ ) quasars have more optical and X-ray continuum than the lobe-dominated quasars<sup>11,20</sup>. We find a similar result using our data. The

hypothesis that the distributions of continuum luminosity are identical can be rejected by the Kolmogorov-Smirnov test at the 95% level. Our conclusion is that, in addition to some isotropic emission, there is a component of quasar continuum that depends systematically on orientation.

There are at least two ways of producing directionally dependent continuum emission: by relativistic beaming of non-thermal radiation<sup>7,8</sup> or by thermal radiation from an optically thick disk whose axis is parallel to the radio axis<sup>1</sup>. These two effects dominate over different ranges of  $R$ : relativistic beaming dominates for  $R \geq 1$ , and disks for  $R \leq 1$ . Although we would argue that relativistic beaming is responsible for the extra brightness of high- $R$  objects, sometimes leading to blazar activity, whether or not the effects of directionally dependent disk radiation are noticeable at low  $R$  remains to be investigated.

Finally we consider whether objects that do not satisfy our quasar selection criteria should be added to Fig. 1. At one extreme there are BL Lac objects, whose lines are generally too weak to allow measurement of their redshift. These objects would appear in the lower right area of Fig. 1 because they are invariably core-dominated. We strongly suspect that at least some of these objects should be included with the quasars, and this inclusion would obviously reinforce the observed anticorrelation. At the other extreme lie radio galaxies, objects with very high equivalent widths and, usually, very low  $R$ . It has been argued<sup>21,22</sup> that these objects should also be considered as quasars, with their radio axes in the plane of the sky and their nuclear continuum sources and broad-line regions obscured. Although adding them to Fig. 1 would greatly increase the significance of the correlation, we feel that the case for inclusion of these objects has yet to be fully established.

We conclude that the similarity of [0111] strengths in core- and lobe-dominated quasars of the same extended radio luminosity supports models in which the only difference between the two types of quasar is viewing angle, together with the consequent Doppler beaming. The natural interpretation of our equivalent width:  $R$  anticorrelation is therefore that the optical continuum is anisotropic. This is an important result, for two reasons. First, emission models must take into account the fact that the different parts of the line-emitting region may see very different photo-ionizing continua. And second, the assumption that selection of quasars by optical brightness leads to samples with a random distribution of orientation angles<sup>23</sup> may not be valid.  $\square$

## Impact erosion of the primordial atmosphere of Mars

H. J. Melosh & A. M. Vickery

Lunar and Planetary Laboratory, University of Arizona, Tucson, Arizona 85721 USA

**ABUNDANT** geomorphic evidence for fluvial processes on the surface of Mars suggests that during the era of heavy bombardment, Mars's atmospheric pressure was high enough for liquid water to flow on the surface. Many authors have proposed mechanisms by which Mars could have lost (or sequestered) an earlier, thicker atmosphere but none of these proposals has gained general acceptance. Here we examine the process of atmospheric erosion by impacts and show that it may account for an early episode of atmosphere loss from Mars. On the basis of this model, the primordial atmospheric pressure on Mars must have been in the vicinity of 1 bar, barring other sources or sinks of  $\text{CO}_2$ . Current impact fluxes are too small to erode significantly the present martian atmosphere.

Although a great deal of effort has been expended on the study of the craters produced by large impacts, little work has been done on the atmospheric effects of impacts. A beginning was made by Walker<sup>1</sup>, who showed that a projectile traversing the atmosphere of a planet could eject at most only a few times the mass of the atmosphere traversed. This conclusion generally agrees with that of Ahrens and O'Keefe<sup>2</sup>, who studied the effects of the airblast produced by the impact and of the early fast ejecta on atmospheric erosion. Previously<sup>3</sup> we used an analytical model to show that fast solid ejecta from the crater are similarly

FIG. 1 Threshold impact velocity for some (light line) and most (heavy line; from equation (1) of the text) of the vapour produced in an impact to reach escape velocity of the planet on which it strikes: a, for silicate projectiles; b, for ice projectiles.

Unger, P. Murdin and D. King for help with the observations. N.J. is grateful for a Samuel Gratrix postgraduate studentship.

unable to eject more than a few times the atmospheric mass traversed by the projectile. However, we show here that the vapour plume created by high-speed impacts is extremely effective in ejecting atmospheric gases—for sufficiently large impacts the vapour plume may eject the entire airmass above the plane tangent to the point of impact, a result in general conformity with those of refs 4 and 5. Atmospheric erosion by impacts may therefore play an important part in the evolution of atmospheric pressure, especially on Mars because of its low gravity and small radius.

Although much of our work is based on detailed computer modelling, it is easy to construct a simple analytical model of atmospheric erosion by impacts that seems to capture most of the essentials of the process. Only a few basic equations are needed if one is willing to overlook uncertainties and subtleties that could change the results by factors of about two. The first essential feature for atmospheric erosion to occur is that the projectile must strike the planet with enough velocity for a vapour plume to form. The plume must also expand at a speed faster than the planet's escape velocity,  $v_{\text{esc}}$ . A model of vapour-plume expansion<sup>6</sup> gives the mean (mass-averaged) velocity of expansion as  $[2(E - H_{\text{vap}})]^{1/2}$ , where  $E$  is the specific energy of the vaporized projectile and target material and  $H_{\text{vap}}$  is the vaporization energy, taken here to be 13 MJ kg<sup>-1</sup> for silicates and 3 MJ kg<sup>-1</sup> for ice. The maximum expansion velocity of the gas cloud is approximately a factor  $[2\gamma/(\gamma - 1)]^{1/2}$  ( $=2.82$  for  $\gamma = 4/3$ , where  $\gamma$  is the ratio of specific heats) times faster than this, so use of the mean velocity is a conservative assumption. The specific energy  $E$  is, from the Hugoniot equations, equal to  $u^2/2$ , where  $u$  is the particle velocity behind the shock. The maximum particle velocity  $u$  is  $v/2$ , where  $v$  is the impact velocity, by the planar impact approximation when both target and projectile are nearly the same material, so  $E \approx v^2/8$ . After a little algebra, the threshold impact velocity  $v_{\text{min}}$  for most of a vapour plume to exceed escape velocity can be shown to be

$$v_{\text{min}} = \sqrt{8 \left( \frac{v_{\text{esc}}^2}{2} + H_{\text{vap}} \right)} \quad (1)$$

Figure 1 illustrates this threshold for both silicate and icy projectiles, along with the more optimistic threshold at which some of the expanding vapour plume reaches escape velocity. We believe the more conservative limit in equation (1) is to be preferred for atmospheric-loss computations.

In the case of Mars,  $v_{\text{min}}$  is 14.3 km s<sup>-1</sup> for silicate impactors and 11.1 km s<sup>-1</sup> for icy impactors. These minima are less than the estimated r.m.s. impact velocities<sup>7</sup> with either Earth-crossing asteroids (19 km s<sup>-1</sup>), periodic comets (21 km s<sup>-1</sup>), or parabolic comets (42 km s<sup>-1</sup>). It is slightly larger than the mean impact velocity<sup>8</sup> with Mars-crossing asteroids (10 km s<sup>-1</sup>). Here we assume that the flux of impactors fast enough to produce a vapour plume that exceeds Mars's escape velocity is half of the total flux. During accretion, impact velocities were undoubtedly

lower so that at that time Mars could have accumulated its original atmosphere.

The second factor in estimating whether or not an impact can remove the atmosphere is that if the vapour plume is to carry away the atmosphere, the mass of vapour from projectile and surrounding vaporized target (if any) must exceed the airmass  $m_p \approx 2\pi P_0 HR/g$  above the plane tangent to the impact. This relation is supported by our more detailed numerical studies. Thus, we take

$$m_* \geq \frac{2\pi P_0}{g} HR \quad (2)$$

where  $m_*$  is the projectile mass just capable of removing the atmosphere above the tangent plane,  $P_0$  is the surface atmospheric pressure,  $g$  is the acceleration of gravity,  $R$  is the radius of the planet, and  $H$  is the atmospheric scale height. In equation (2) it is assumed that the projectile and an equal mass of the target are vaporized and shocked to the same total internal energy. Although other assumptions could be made, this is one of the most conservative because it neglects a possibly significant quantity of vaporized target that may expand fast enough to reach escape velocity itself.

A potentially important effect neglected in equation (2) is the concentration of atmospheric mass at low angles from the horizon. The vapour plume expands nearly hemispherically, and thus may couple inefficiently to the atmospheric mass which is concentrated toward the horizon. Note that after the vapour plume has expanded to a few tens of the projectile diameter, adiabatic cooling condenses much of the vaporized rock into a dense, fast-moving dust cloud that follows nearly ballistic trajectories and sweeps the ambient atmosphere before it. This effect is largest for small values of  $H/R$ . Our detailed numerical computations suggest that this effect is minimal for Mars, but could be important for the Earth or Venus.

For Mars, the smallest projectile that can remove the entire airmass above the tangent plane at the present time is  $\sim 4 \times 10^{13}$  kg, or a silicate object  $\sim 3$  km in diameter. Note that equation (2) does not take account of possible enhanced vaporization in oblique impacts — such an angle-dependent phenomenon might reduce  $m_*$  by a factor of perhaps five.

These results for the mass of the projectile necessary to remove the atmosphere above the tangent plane must be supplemented with the flux of projectiles to compute the evolution of atmospheric pressure with time. The present cumulative flux (number s<sup>-1</sup> m<sup>-2</sup>) of projectiles with mass greater than or equal to  $m$  is parameterized by  $N_{\text{cum}}(m) = am^{-b}$ , where  $a$  and  $b$  are constants. Unfortunately, neither the overall flux,  $a$ , nor the slope of the distribution,  $b$ , are well-known. Values of these constants that predict the correct present lunar crater distribution via the revised Schmidt-Holsapple scaling law<sup>9</sup> are  $a = 1.55 \times 10^{-23}$  kg<sup>b</sup> m<sup>-2</sup> s<sup>-1</sup>,  $b = 0.47$ . The slope of the crater distribution on the martian plains is the same as the lunar distribution<sup>10,11</sup>, and the overall cratering rate on Mars at present is

FIG. 2 Comparison between the lunar impact crater density and that predicted by the flux model of equation (5). The revised Schmidt-Holsapple scaling relations for silicate projectiles<sup>9</sup> were used to equate the flux to a crater density assuming an average impact velocity of 20 km s<sup>-1</sup>, mean impact angle of 45°, and a rim-to-rim diameter 25% larger than the apparent transient crater diameter. This yields a cumulative crater density for craters  $> 4$  km diameter of  $N(> 4 \text{ km}) = 2.68 \times 10^5 [T + 4.57 \times 10^{-7} (e^{\lambda T} - 1)]$ , where  $T$  is the age of the cratered surface and  $\lambda = 4.53 \text{ Gyr}^{-1}$ . Crater density data from the compilation in ref. 7, Table 8.4.2.

estimated to between one and four times the lunar rate, with a preferred mean of about two (ref. 7).

Using this constant cratering rate, the rate of mass loss from a planet's atmosphere  $dM_{\text{atm}}/dt$  is given by the flux  $N_{\text{cum}}(m_*)$  of projectiles large enough to remove the atmosphere above the tangent plane, multiplied by the planet's surface area  $4\pi R^2$ , multiplied by the mass above the tangent plane  $m_{\text{tp}} = M_{\text{atm}}(H/2R)$  for  $R \gg H$ . As  $m_*$  itself depends upon  $M_{\text{atm}}$ , a simple differential equation for  $M_{\text{atm}}$  (or, equivalently,  $P$ ) results, whose solution, converted to a convenient and universal form, is:

$$\frac{M_{\text{atm}}(t)}{M_0} = \frac{P(t)}{P_0} = \left(1 - \frac{t}{t_*}\right)^{1/b} \quad (3)$$

where  $M_0$  is the present ( $t=0$ ) atmospheric mass,  $P_0$  is the present atmospheric pressure and  $t_*$  is the length of time required for impacts to reduce the atmospheric pressure to zero. In terms of previously defined quantities,

$$t_* = \frac{1}{2\pi ab(RH)^{1-b}} \left(\frac{2\pi P_0}{g}\right)^b \quad (4)$$

Note that the above equation for the time dependence of atmospheric mass or pressure can be used for times before the present ( $t < 0$ ), so that the atmospheric pressure at any previous era can also be computed. It is interesting to note that the atmospheric pressure declines rigorously to zero at time  $t_*$ —it does not simply fall exponentially towards zero. This interesting fact (K. Zahnle, personal communication) is a unique characteristic of the impact erosion mechanism. As the atmospheric pressure declines, smaller projectiles are capable of removing the atmosphere above the tangent plane. But by the distribution law, there are more smaller projectiles than larger ones, so a greater fraction of the atmosphere is removed in each unit time interval. The net result is the complete stripping of the atmosphere after time  $t_*$ , barring volcanic or other sources of replenishment.

The post-late-heavy-bombardment flux, along with other parameters, gives a value of  $t_* \approx 60$  Gyr for Mars at the present time (note that  $t_*$  for the Earth and Venus is longer by several orders of magnitude, so that the impact erosion of their atmospheres is entirely negligible). Although this number is quite uncertain, it should probably be regarded as an upper limit, as the enhancement of vaporization by oblique impact and a possible large admixture of cometary impacts in the martian cratering flux both tend to shorten  $t_*$ . The adopted value for  $t_*$  predicts an atmospheric pressure at the end of late heavy bombardment (3.2 Gyr) only 1.1 times the present low pressure. This would not explain the geomorphic evidence<sup>12</sup> for running water on Mars's surface early in its geological history. It is widely known<sup>7</sup>, however, that the impact flux on the Moon in the first  $10^9$  years

FIG. 3 Evolution of the atmospheric pressure  $P(t)$  on Mars relative to its present value  $P_0$ . This figure is constructed using equation (6) assuming  $t_* = 63.1$  Gyr,  $B = 2,300$  and  $\lambda = 4.53 \text{ Gyr}^{-1}$ . It shows the rapid decline in Mars's atmospheric pressure throughout the era of late heavy bombardment.

of its history was many orders of magnitude larger than at present. It is presumed<sup>11</sup> that Mars, too, shared in this era of 'heavy bombardment', so that the enhanced impact fluxes of this era may have produced an early period of rapid atmospheric-pressure change. The heavy bombardment flux can be adequately described by

$$N_{\text{cum}}(m, t) = a(1 + B e^{-\lambda(t+4.6)})m^{-b} \quad (5)$$

where  $a$  and  $b$  are the same as before,  $B = 2,300$  and  $\lambda = 4.53 \text{ Gyr}^{-1}$ . Figure 2 shows that the crater density computed by this expression provides an excellent fit to the lunar data as far back as 4.4 Gyr.

The differential equation for the rate of atmospheric mass loss implied by equation (5) can be readily integrated, giving a simple analytic expression similar to equation (3) for the evolution of atmospheric pressure as a function of time  $t$  from the present:

$$\frac{M_{\text{atm}}(t)}{M_0} = \frac{P(t)}{P_0} = \left(1 - \frac{t}{t_*} - \frac{B e^{-4.6\lambda}}{\lambda t_*} [1 - e^{-\lambda t}]\right)^{1/b} \quad (6)$$

The atmospheric pressure of Mars predicted by this expression is shown in Fig. 3. It is clear that early in Mars's history its atmospheric pressure must have been at least 100 times its present value, that is,  $\sim 1$  bar. Note that this pressure is near that considered necessary for Mars to have supported free water on its surface<sup>13</sup>.

The simple analytical model of atmospheric erosion described here clarifies several aspects of martian climatic history. First, it is important to emphasize that the present atmosphere of Mars is stable against atmospheric erosion on the timescale of several tens of Gyr. Second, the impact flux during the era of late heavy bombardment was so high that Mars must have had a primordial atmospheric pressure near 1 bar: otherwise, its present atmospheric pressure would be even lower than it is now. This observation agrees well with the geomorphic evidence for fluvial processes during the era of heavy bombardment and with the more indirect evidence<sup>14</sup> for an early era of enhanced erosion that erased small craters and obliterated the rims and other details of larger ones. Mars was able to accumulate its primordial atmosphere in the first place because impact velocities during accretion were too low for the vapour plumes to reach escape velocity. Note that impact erosion does not fractionate atmospheric constituents: a sufficiently large, fast impact removes the atmosphere completely, preserving the ratios of gaseous species while reducing their absolute abundance. However, a condensable substance such as water might be preserved on the surface while other atmospheric constituents are ejected. This property of impact erosion may go far in explaining some of the apparent differences in the atmospheric rare-gas inventories of Mars and the Earth. Our model makes it clear that of all the terrestrial planets, Mars is peculiarly susceptible to impact erosion because of its small radius and low gravitational acceleration. Application of the same model to the Earth indicates a primordial atmospheric pressure about 6 times its present value, whereas Venus would have had an initial atmosphere of only  $\sim 1.5$  times its present pressure.  $\square$

**TRENDS** of increasing atmospheric methane, carbon dioxide and other species have now been identified<sup>1</sup>. It is well-known that water vapour is an important product of methane oxidation in the stratosphere<sup>2,3</sup> and here we investigate the possibility that a substantial change has occurred in middle-atmospheric water vapour as a result of the increase in methane over the past century and a half. We show from modelling of mesospheric ice-particle formation that noctilucent cloud brightness should be a sensitive indicator of the water content at the high-latitude summertime mesopause (at a height of 85 km). Blake and Rowland<sup>4</sup> have recently suggested that the occurrence of polar stratospheric clouds may be increasing because of increasing methane. We look at the record of noctilucent cloud occurrence for which the historical record is more complete. We find that noctilucent clouds are absent from the historical record before 1885, which is consistent with our hypothesis.

The hypothesis that upper atmospheric water vapour is increasing because of increases in methane is testable by the consequent effect on noctilucent-cloud (NLC) brightness, which has been recorded for over a century. Our model<sup>5</sup> of NLC ice-particle formation and growth shows quantitatively that cloud brightness may indeed be a sensitive indicator of water-vapour concentration. In view of this, it is remarkable that, despite the fact that observations of NLCs have been made almost every year since their discovery in 1885, none were observed before this date, notwithstanding the attention of a number of skilled observers, located at the appropriate latitudes, who were sufficiently familiar with twilight phenomena. Using our NLC model, we show that clouds were probably not detect-

able in previous centuries because of their weakness compared with the twilight background. Alternatively, however, the discovery of NLCs may have been prompted by the Krakatoa volcanic eruption two years before, which would have caused volcanic injection of water into the stratosphere, followed by slow upward transport to the summertime mesopause. Nevertheless, we expect that the principal cause of most modern NLCs is the current high level of methane-derived water vapour.

Evidence that pre-industrial methane levels were about one half that of the present comes from measurements of reduced methane concentrations within air bubbles trapped in polar ice<sup>6</sup>. Biological sources of methane include anaerobic bacterial fermentation in rice fields, natural wetlands, landfills, domesticated animals (ruminants), and termites. Non-biological sources are natural-gas leaks and venting, mining activities, and industrial activities of several types. The major sink of atmospheric methane is the reaction with the hydroxyl radical (OH). Although the methane budget is not well understood<sup>7</sup>, the globally rising trend is probably a consequence both of increasing source strength (because of increased land use and increasing human and animal populations) and of a global reduction in atmospheric OH levels<sup>8</sup>.

Methane is nearly fully mixed in the troposphere because of its long lifetime (~8 years)<sup>7</sup>. Tropospheric gases are believed to enter the stratosphere in the tropics<sup>9</sup>, although important details of the processes involved are not yet understood<sup>1</sup>. Distribution of methane throughout the stratosphere and mesosphere takes about 2–3 years (ref. 10).

At present, methane oxidation accounts for about one half of the total water above the tropopause<sup>11</sup>. We define total hydrogen as  $[H]_t = [H_2O] + 2[CH_4] + [H_2]$ , where the bracket  $[ ]$  denotes mole fraction or mixing ratio. As there are no sources or sinks of  $[H]_t$  in the upper stratosphere and mesosphere (height of 30–90 km), it is a conserved quantity throughout this region. Thus it is possible to infer changes in water vapour at the high-latitude summer mesopause without the use of a detailed model of atmospheric transport.

Stratospheric methane is slowly removed by complex reactions with OH and with excited atomic oxygen,  $O(^1D)$ , resulting in the production of water, molecular hydrogen and negligible amounts of odd-hydrogen radicals<sup>12</sup>. The expectation that roughly two  $H_2O$  molecules are produced for every  $CH_4$  molecule destroyed has been confirmed by satellite observations of water vapour and methane<sup>11</sup>. Methane oxidation occurs mainly above 30 km, and repartitions  $[H]_t$  primarily into  $H_2O$

FIG. 1 a, Noctilucent cloud brightness versus water vapour mixing at the lower boundary of the microphysical model. Brightness is measured in terms of the directional albedo<sup>31</sup>, that is, the apparent emission rate divided by the solar flux at a wavelength of 555 nm. The elevation angle of observation and the solar depression angle are both assumed to be 11°. The four curves apply to different values of the mesopause temperature minimum:  $T_m = 130, 132, 134$  and  $136$  K. The Rayleigh-scattered background albedo corresponds

to the viewing conditions assumed in the NLC albedo calculations. Also shown are measurements of the current NLC brightness ( $\Delta$  ref. 32;  $\diamond$  ref. 33;  $\square$  ref. 34; \* ref. 35). b, Noctilucent cloud brightness versus time, in years relative to the present. The values of water vapour were taken from Table 1, and the corresponding values of cloud brightness were taken from the 134-K curve of a.

and  $H_2$ . In the high-latitude summer,  $[H]_t$  consists almost entirely of  $H_2O$ , at concentrations of about 6 p.p.m. by volume  $p$  to about 70 km. A pronounced vertical gradient of  $[H_2O]$  occurs in the upper mesosphere through the progressive photolytic destruction of  $H_2O$  (ref. 13). In this region,  $H_2$  is formed from photolytic reactions among the products of water-vapour dissociation, which consist of odd-hydrogen free radicals. At the high-latitude summer mesopause, the partitioning of  $H_2O$  and  $H_2$  is predicted<sup>12</sup> to be about equal, at 2 p.p.m.v.

With a current atmospheric mixing ratio of  $\sim 1.65$  p.p.m.v.,  $CH_4$  contributes about 55% of the total hydrogen<sup>11</sup>. The remaining 2.7 p.p.m.v. (or 45%) is derived from tropospheric/oceanic sources of  $H_2O$ . Assuming that the latter sources are constant in time, we may calculate the time variation of the water-vapour mixing ratio at 70 km that results from increasing methane levels. Table 1 shows the results calculated using the methane levels reported from ice bubble analyses<sup>6</sup>. As recently as 100 years ago, the  $H_2O$  level may have been only 4.5 p.p.m.v., as opposed to the current value of 6 p.p.m.v.

The current levels of  $H_2O$ —6 p.p.m.v. at 70 km and  $\sim 2$  p.p.m.v. at the high-latitude summer mesopause—are sufficient to explain NLC brightness on the basis of particle growth modelling<sup>14</sup>. It is necessary that the mesopause temperature,  $T_M$ , be less than 135 K so that supersaturation conditions are met at these very low humidities<sup>15</sup>. Water-ice particles are nucleated near the mesopause by meteoric dust and/or by heavy-water cluster ions<sup>14</sup>. Several factors control the NLC brightness in our one-dimensional model, namely temperature and pressure at the mesopause, water-vapour mixing ratio, vertical diffusion rate, and vertical wind speed<sup>5</sup>. Unfortunately, none of these properties is well-known, and in addition they are probably variable from day to day. They must be treated as parameters in the model. Most relevant here is the dependence of cloud brightness on amount of water vapour and on mesopause temperature.

Shown in Fig. 1a are the model calculations of maximum NLC albedo plotted for a range of water-vapour mixing ratios at the lower boundary height of 70 km. We calculate  $H_2O$  concentrations above the lower boundary height by a combination of advective and diffusive transport, photolysis, and sublimation onto and from ice particles. The various curves correspond to different values of  $T_M$ , selected to fall within the observed range. Note that  $[H_2O]$  at the observed height of NLCs (83 km) will be appreciably less than 6 p.p.m.v., because of solar photodissociation and depletion by growing ice particles. Also indicated in Fig. 1a is the range of NLC albedos reported in the literature.

For fixed  $T_M$  the model cloud brightness is very sensitive to  $[H_2O]$ , changing by more than an order of magnitude over a small range in humidity. This sensitivity is caused by the increase in particle growth rate, and resulting maximum particle size, with increasing  $H_2O$  concentration. The scattered radiance depends strongly on the effective particle radius  $r$  (being proportional to  $r^\alpha$ , with  $\alpha \approx 5-6$ ). These factors combine to yield a cloud radiance that scales as  $[H_2O]^\beta$ , with  $\beta \approx 2-3$  (ref. 5). However, this scaling law was derived by assuming a fixed number of cloud particles,  $n$ . In our model, we use a nucleation scheme<sup>14</sup> in which ice deposition occurs only on dust particles whose radius exceeds a critical value. For a fixed temperature, this critical radius decreases with increasing  $H_2O$  concentration. Because the concentration of dust particles increases sharply with decreasing radius, a small increase in  $H_2O$  concentration results in a large increase in the number of particles nucleated. The combined effects of increasing both the numbers and the sizes of cloud particles explains the strong sensitivity of NLC brightness to  $[H_2O]$ . This new model yields values of the exponent,  $\beta$ , that vary between 4 and 8, depending on various model parameters.

Based on the trend of  $[H_2O]$  in Table 1, the evolution of NLC brightness with time is shown in Fig. 1b, along with the calculated Rayleigh-scattered background albedo. We show the results for

$T_M = 134$  K only, but the same general behaviour would be seen at other temperatures.

We now ask whether NLCs were likely to have been present but unnoticed in earlier years. The first observation of NLCs was made by Backhouse<sup>16</sup> on 8 June 1885 in Bad Kissingen, Germany. Some days later this phenomenon came to the attention of numerous astronomers and meteorologists throughout Europe, Great Britain<sup>17</sup> and in Russia<sup>18</sup>. Certain individuals confessed explicitly to have never seen NLCs before this date<sup>19-27</sup>. Some reports of twilight enhancements before 1885 may be attributed to the phenomenon of 'bright nights', that is, enhanced airglow emission, which has been seen at all latitudes and seasons.

Evidence that NLCs were not observed before 1885 is not conclusive. If, however, a pre-1885 sighting of NLCs were to be confirmed, our hypothesis would not necessarily be damaged; we argue only that such sightings were much less likely than they are today. In fact, we believe that the very first sighting was probably not due to the slow emergence of NLCs above the sky background, but that the upper atmosphere probably received an added 'boost' of condensation nuclei and/or water vapour from the Krakatoa volcanic eruption in 1883. The two-year time delay is consistent with the time needed to transport material from the stratosphere to the upper mesosphere<sup>28</sup>, and has been verified by recent model calculations<sup>10</sup>. From Fig. 1a, an abrupt enhancement in NLC brightness would require an injection of 1-2 p.p.m.v. of  $H_2O$ . Assuming that the water was injected at the observed height of the Krakatoa dust plume, a 1-2 p.p.m.v. increase corresponds to a total additional water mass of 100-200 megatons. (The mass of sulphate injected into the stratosphere by Krakatoa has been estimated to be 100 megatons<sup>36,37</sup>.)

We believe that most of the NLC sightings over the past century can be ascribed to the increased water levels arising from methane oxidation. The periodic rise and fall of NLC activity on shorter timescales (decades) is probably due to shorter-term fluctuations in the controlling factors, the most important being material supplied by volcanic injections<sup>29</sup>.

A direct and important inter-relationship between methane, water vapour and the existence of ice clouds in the middle atmosphere is plausible, but what are the long-term implications? In Table 1 and Fig. 1b we have extrapolated forward in time the curves representing water vapour and NLC brightness. We expect brighter and more widespread displays with longer seasons of occurrence. In fact, Gadsden<sup>30</sup> suggests, on the basis of observations made over the last three decades, that both NLC occurrence frequency and the duration of the NLC 'season' have increased. However, the trend that we would predict over this time interval is much less dramatic than Gadsden's. Furthermore, the time series used in ref. 30, derived from observations in northern Europe, does not agree well with corresponding

TABLE 1 Estimated time history of tropospheric methane and high-latitude mesospheric water vapour

Years (before present)	Methane surface concentration (p.p.m.v.)	Water vapour at 70 km (p.p.m.v.)
150	0.8	4.3
100	0.9	4.3
100	0.9	4.5
50	1.2	5.2
0	1.65	6.0
-50	2.7	8.1

The trends of methane up to the present time is taken from Fig. 1 of ref. 6. Mesospheric water vapour is assumed to originate from the atmospheric/oceanic source of 2.7 p.p.m.v. plus a source from methane oxidation (one  $CH_4$  molecule produces two  $H_2O$  molecules). At 70 km, total hydrogen  $[H]_t$  is assumed to be primarily in the form of  $[H_2O]$ . The future trend for methane is taken to be 1.3% per year.

data from the USSR, so that the reported trend may be of regional but not global significance.

It is unlikely that the current atmospheric structure and dynamics will remain unchanged in the face of the important compositional changes taking place throughout the atmosphere. In particular, reductions in ozone and increases in carbon dioxide will alter both the thermal and dynamic structure of the entire middle atmosphere. As noctilucent clouds are probably under strong dynamic control, even small perturbations could be important.

We conclude the following: (1) the first manifestation of the noctilucent cloud phenomenon occurred in the summer of 1885

in northern Europe; (2) before 1885 there was insufficient water vapour routinely available at the mesopause to form visible clouds; (3) the NLC sightings during the period 1885–1895 were probably made possible in part by the large stratospheric injections of water vapour that resulted from the Krakatoa eruption in 1883; (4) the increase in water from methane oxidation will continue in the immediate future, increasing the occurrence frequency and brightness of NLC; and (5) in the long term, the continued rise of trace substances in the atmosphere will act to change the structure and transport within the middle atmosphere in ways that are extremely difficult to predict, making the future of NLC behaviour uncertain. □

## Limitations on the rapid reduction of nitrogen oxides in exhaust gas streams

Brian G. Wicke, Karen A. Grady & John W. Ratchliffe

Physical Chemistry Department, General Motors Research Laboratories, Warren, Michigan 48090, USA

ALL commercially important combustion systems produce exhaust gases containing substantial amounts of nitrogen oxides and molecular oxygen. Because of the part played by nitrogen oxides in smog formation and acid-rain production, methods of reducing  $\text{NO}_x$  emissions have been subject to intense research. In 1986, Perry and Siebers<sup>1</sup> proposed a new chemical method for removing  $\text{NO}_x$  from diesel exhaust gas by adding cyanuric acid ( $\text{HNCO}$ )<sub>3</sub>, and suggested that this new process, called RAPRENOx (rapid reduction of  $\text{NO}_x$ ) could control the emission of  $\text{NO}_x$  from most combustion devices. Here we show that surface chemistry is responsible for the effective reduction of  $\text{NO}_x$ , confirming recent results<sup>2</sup>. In stainless steel, in the absence of oxygen,  $\text{NO}$  is effectively reduced by cyanuric acid at 700 °C. When oxygen is present, however,  $\text{NO}$  is produced by the reaction with cyanuric acid at 700 °C. Under conditions where surface effects are important (such as in the first demonstration experiments reported on RAPRENOx) the reduction of  $\text{NO}$  by cyanuric acid is adversely affected by oxygen.

To learn more about the chemistry involved in RAPRENOx, we carried out a series of laboratory flow-tube experiments under conditions similar to those reported initially<sup>1</sup>. We used two different flow tubes, one quartz and the other stainless steel; except for this difference in material, the two flow tubes were identical (22 mm inner diameter, 80 cm long). Pure gases ( $\text{Ar}$ ,  $\text{NO}$ ,  $\text{CO}$ ,  $\text{CO}_2$ ,  $\text{O}_2$ ,  $\text{H}_2$ ,  $\text{N}_2$  and  $\text{N}_2\text{O}$ ) were admitted to the flow tube through calibrated electronic flow controllers. The flow tube has two independently controlled heated sections: a pre-

heater section (20 cm long) and a reaction section (25 cm long) immediately downstream. Cyanuric acid was sublimed from a quartz crucible lowered into the centre of the preheater region; adjusting the preheater temperature provided independent control of the cyanuric acid sublimation rate.

A mass spectrometer sampled the gas flow downstream of the reaction region. The mass spectrometer sensitivity for the gases of interest was measured before and after each experiment using known flows of the pure gases. Water was also observed in these experiments; because of problems related to  $\text{H}_2\text{O}$  condensation on the flow tube walls, no attempt was made to measure  $\text{H}_2\text{O}$  quantitatively.  $\text{Ar}$  was the predominant gas (>95%). Typical conditions were: pressure 28 kPa; reactor temperature 700 °C; residence time at 700 °C = 1 s. These conditions were chosen to approximate those of the earlier study<sup>1</sup>.

In the quartz flow tube, most of the cyanuric acid which sublimed in the preheater region deposited out onto the cool flow-tube walls downstream of the 700 °C reaction. A small fraction of the cyanuric acid did decompose; the observed decomposition products included  $\text{HNCO}$ ,  $\text{CO}$ ,  $\text{CO}_2$ ,  $\text{N}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{NH}_3$  and  $\text{HCN}$ . Addition of  $\text{NO}$  upstream of the cyanuric acid produced no change in the thermal decomposition of cyanuric acid, and no reduction of  $\text{NO}$  was observed.

In the otherwise equivalent stainless-steel flow tube, cyanuric acid decomposed rapidly at 700 °C; no solid deposits were observed on the flow-tube walls. The decomposition products were  $\text{CO}$ ,  $\text{H}_2$  and  $\text{N}_2$ , and a small amount of  $\text{CO}_2$ . We analysed the mass spectrometer data and determined the overall stoichiometry of this fast thermal decomposition in stainless steel as:

The small amount of  $\text{CO}_2$  observed results at least in part from the oxidation of  $\text{CO}$  on the walls of the heated flow tube. The independently measured sublimation of cyanuric acid agreed well with the amounts of H, N and C measured in  $\text{H}_2$ ,  $\text{N}_2$  and  $\text{CO} + \text{CO}_2$ .

In stainless steel at 700 °C, we observed the rapid reduction

of NO by cyanuric acid. The chemistry is represented by the following stoichiometry:

All species were measured independently except  $\text{H}_2\text{O}$ . No  $\text{N}_2\text{O}$  was observed. The 1-s residence time at  $700^\circ\text{C}$  was sufficient for complete reaction. These observations of the importance of surface chemistry confirm recent findings<sup>2</sup>. Experiments to identify the role of the surface interactions are in progress.

We also find that cyanuric acid reacts rapidly with  $\text{O}_2$  at  $700^\circ\text{C}$  in stainless steel. Our quantitative measurements are consistent with the following overall stoichiometry:

This does not represent the molecular kinetics, of course; it is simply a balanced relationship between major reactants fed into the reactor and major products observed downstream. NO is the major nitrogen-containing product.

The competition for limiting cyanuric acid between NO and  $\text{O}_2$  is illustrated by the sequence of mass spectra shown in Fig. 1. The top mass spectrum is for gas flow of 5.0 standard  $\text{cm}^3 \text{min}^{-1}$  of NO and 2.0 standard  $\text{cm}^3 \text{min}^{-1}$   $\text{O}_2$  in argon at  $700^\circ\text{C}$  in stainless steel. The centre mass spectrum shows the downstream species observed upon addition of 5.0 standard  $\text{cm}^3 \text{min}^{-1}$  NO to limiting cyanuric acid sublimation; note the excess NO at 30 AMU. The bottom mass spectrum shows the addition of 2.0 standard  $\text{cm}^3 \text{min}^{-1}$   $\text{O}_2$  to this NO/limiting cyanuric acid flow. Oxygen is consumed (32 AMU) and more NO is observed than was input (top). In limiting cyanuric acid,  $\text{O}_2$  reacts more rapidly than NO under these conditions.

This seems to contradict the original diesel experiment which purported to demonstrate that RAPRENOx was effective in a stainless-steel system in the presence of excess oxygen<sup>1</sup>. We believe, however, that the diesel data support the  $\text{O}_2$  sensitivity

we observe. In the diesel experiment, NO increased by a factor of at least 25 as the cyanuric acid bed temperature was raised to  $\sim 340^\circ\text{C}$ ; further increase in the acid-bed temperature produced a rapid decrease of NO. As the acid-bed temperature was raised, cyanuric acid sublimed more rapidly and more reactant was entrained into the gas stream. Starting with limiting cyanuric acid in the oxygen-containing exhaust stream, NO was produced according to reaction (3); increasing the cyanuric-acid sublimation rate produced more NO by reaction (3) until the oxygen (which could not be detected by the Fourier transform infrared technique used<sup>1</sup>) was consumed. Subsequent further increase in the cyanuric acid sublimation rate led to a decrease in the total NO by reaction (2).

For the conditions we have examined and the conditions originally reported in support of RAPRENOx<sup>1</sup>, surface effects are responsible for rapid reduction of NO by cyanuric acid. Under these conditions, however, NO is produced when  $\text{O}_2$  is present. D. L. Siebers and J. A. Caton (personal communication), as well as Heap *et al.*<sup>2</sup>, have reported NO reduction using cyanuric acid under conditions where the surface effects examined here are not important. This gas-phase NO reduction chemistry is sensitive to temperature and the presence of other gases in the exhaust (ref. 2; D. L. Siebers and J. A. Caton, personal communication). The use of the RAPRENOx technique to control  $\text{NO}_x$  emissions seems therefore to be considerably more limited than was suggested originally<sup>1</sup>. □

## Glacial–Holocene salinity changes in the Mediterranean Sea: hydrographic and depositional effects

Robert C. Thunell & Douglas F. Williams

Department of Geological Sciences, University of South Carolina, Columbia, South Carolina 29208, USA

OXYGEN isotope changes as recorded by Pleistocene foraminifera from open-ocean sediments are primarily a function of changes in the isotopic composition of the global seawater reservoir caused by ice-volume changes, with a secondary temperature component<sup>1</sup>. Oxygen isotope records from marginal basins such as the Gulf of Mexico<sup>2</sup>, the Mediterranean Sea<sup>3–5</sup> and the Red Sea<sup>6</sup> also exhibit the global signal but are far more complicated owing to the strong overprint of local climate conditions. In particular, glacial–interglacial changes in continental aridity and river runoff produce significant salinity changes in these semi-enclosed basins. Using available oxygen isotope records we estimate that glacial (18,000 yr BP) salinities in the eastern and western Mediterranean Sea were 2.7‰ and 1.2‰ higher, respectively, than at present. These elevated glacial salinities played an important part in preconditioning the eastern Mediterranean for the eventual accumulation of organic carbon-rich sediments (sapropels) at the end of deglaciation.

Our database consists of thirty published planktonic foraminiferal oxygen isotope records from the eastern and western basins of the Mediterranean (Table 1; refs 7–17). For each record, the magnitude of the oxygen isotope change has been estimated for three different intervals: (1) from 18,000 yr BP to present, (2) from 18,000 yr BP to 8,000 yr BP, and (3) from 8,000 yr BP to present (Table 1). The 8,000 yr BP level represents

FIG. 1 Mass spectra showing the competition for limiting cyanuric acid between NO and  $\text{O}_2$  at  $700^\circ\text{C}$  in stainless steel. a, NO = 5.0 standard  $\text{cm}^3 \text{min}^{-1}$ ,  $\text{O}_2$  = 2.0 standard  $\text{cm}^3 \text{min}^{-1}$ , no cyanuric acid sublimation. b, NO = 5.0 standard  $\text{cm}^3 \text{min}^{-1}$ , no  $\text{O}_2$ , and stable limiting cyanuric acid sublimation. c, Same as b, to which 2.0 standard  $\text{cm}^3 \text{min}^{-1}$   $\text{O}_2$  has been added.

the midpoint (in time) of deposition of the most recent sapropel<sup>8</sup>. For each of these time intervals we estimate how much of the observed isotopic change can be attributed to salinity change ( $\Delta S$ ) using the following equations:

$$\Delta S_1 = (\Delta 18k-P) - V - \Delta T_1 \quad (1)$$

$$\Delta S_2 = (\Delta 18k-8k) - V - \Delta T_2 \quad (2)$$

$$\Delta S_3 = (\Delta 8k-P) - V - \Delta T_3 \quad (3)$$

where  $\Delta S_1$ ,  $\Delta S_2$  and  $\Delta S_3$  are  $\delta^{18}O$  changes (‰) owing to salinity changes for the intervals 18,000 yr BP-present, 18,000 yr BP-8,000 yr BP and 8,000 yr BP-present, respectively.  $\Delta 18k-P$ ,  $\Delta 18k-8k$  and  $\Delta 8k-P$  are the calculated  $\delta^{18}O$  changes for the three time intervals and  $V$  is the glacial-interglacial ice volume contribution to the  $\delta^{18}O$  changes.  $\Delta T_1$ ,  $\Delta T_2$  and  $\Delta T_3$  are the  $\delta^{18}O$  changes attributable to temperature for the three time intervals.

To solve these equations we have assumed that deglaciation was virtually complete by 7,000-8,000 yr BP (refs 19, 20). Therefore, the ice-volume ( $V$ ) contribution to the total  $\delta^{18}O$  change in equations (1) and (2) is assumed to be the same, and the ice-volume component in equation (3) is assumed to be zero. We have also assumed that the warming of surface-water temperatures from glacial to present-day values in the eastern and western Mediterranean was complete by ~8,000 yr BP. This does not imply that there have been no temperature or climatic oscillations in the Mediterranean region during the last 8,000 yr. In fact temperatures were probably warmer during the thermal maximum at ~6,000 yr BP. What we have assumed is that there has been no significant net change in temperature between 8,000 yr BP and present. This assumption is supported by palaeotemperature estimates for the adjacent eastern North

Atlantic<sup>21</sup>. As a result,  $\Delta T_1 = \Delta T_2$  and  $\Delta T_3 = 0$ . From these assumptions equation (3) becomes simplified to:

$$\Delta S_3 = \Delta 8k-P \quad (4)$$

which means that the entire difference in  $\delta^{18}O$  between 8,000 yr BP and present is assumed to be due to salinity changes.

Using the data in Table 1, mean values have been determined for the isotopic changes associated with the three time intervals of interest for both the eastern and western Mediterranean (Table 2a; Fig. 1). The mean  $\delta^{18}O$  changes between 18,000 yr BP and present are very similar, 3.1‰ and 2.9‰ for the eastern and western basins, respectively. In contrast, the isotopic differences between the eastern and western basins for the other two time intervals are relatively large. The  $\delta^{18}O$  difference between 18,000 and 8,000 yr BP is 0.7‰ greater in the eastern basin (4.3‰) than in the western basin (3.6‰). Similarly, the  $\delta^{18}O$  response between 8,000 yr BP and present is 0.4‰ larger in the eastern basin (-1.2‰) than in the western basin (-0.8‰) (Table 2a).

The salinity contribution to the observed oxygen isotope change between any two data points can be determined if reasonable estimates are available for the ice-volume effect and the magnitude of temperature change. The ice-volume effect for the most recent glacial-interglacial transition was between 1.1 and 1.3‰ (ref. 22). For our calculations, an ice volume ( $V$ ) of 1.2‰ is used. Foraminiferal transfer-function estimates of glacial sea surface temperatures in the Mediterranean<sup>23,24</sup> indicate that the western and eastern basins were on average ~6 °C and 4 °C colder than at present, respectively. Using the  $\delta^{18}O$ -temperature relationship of 0.2‰ per °C (ref. 25) means that 1.2‰ and 0.8‰ of the total glacial-interglacial  $\delta^{18}O$  changes ( $\Delta T_1$  and  $\Delta T_2$ ) in the western and eastern basins are a function of temperature.

The salinity component of the observed  $\delta^{18}\text{O}$  changes has been calculated for each of the three time intervals using equations (1), (2) and (4) (Table 2b). To convert the salinity portion of the  $\delta^{18}\text{O}$  change to salinity, we use the modern seawater oxygen-isotope/salinity relationship for the Mediterranean<sup>26</sup>. According to this relationship, a 1‰ change in salinity will result in a 0.41‰ change in seawater  $\delta^{18}\text{O}$ . Using the present-day relationship between seawater oxygen isotopic composition and salinity to estimate past salinities is probably too simple. However, as it is not possible to define such a relationship for the past, using the modern relationship is the most reasonable solution to the problem.

The mean planktonic foraminiferal  $\delta^{18}\text{O}$  changes between the last glacial maximum and the present in the western and eastern basins of the Mediterranean are 2.9‰ and 3.1‰, respectively (Table 2a; Fig. 1). These are considerably larger than the 1.8‰ change recorded in the Atlantic<sup>27</sup>. If 1.2‰ of the mean change is due to ice-volume changes,  $\delta^{18}\text{O}$  residuals of 1.7‰ for the western basin and 1.9‰ for the eastern basin represent the combined effect of temperature and salinity change. An additional 1.2‰ and 0.8‰ of the  $\delta^{18}\text{O}$  residuals for the western and eastern basins are accounted for by glacial sea surface temperatures being 6 °C and 4 °C colder than at present<sup>23,24</sup>. Of the total  $\delta^{18}\text{O}$  changes that are observed between 18,000 yr BP and present, 0.5‰ and 1.1‰ are due to salinity changes in the western and eastern Mediterranean, respectively (Table 2b). These  $\delta^{18}\text{O}$  changes are equivalent to salinity changes of 1.2‰ in the western basin and 2.7‰ in the eastern basin (Table 2b). Typical present-day surface salinities in the western and eastern Mediterranean are 38.2‰ and 38.8‰, respectively. From the oxygen isotope results, we estimate that salinities increased to 39.4‰ in the western basin and 41.5‰ in the eastern basin during the last glacial.

The mean  $\delta^{18}\text{O}$  change between 18,000 yr BP and 8,000 yr BP is 3.6‰ for the western basin and 4.3‰ for the eastern basin (Table 2a, Fig. 1). Under the assumptions that deglaciation and surface-temperature warming were virtually complete by 8,000 yr BP, the salinity contribution to the observed  $\delta^{18}\text{O}$  changes is 1.2‰ for the western basin and 2.3‰ for the eastern basin (Table 2b). These  $\delta^{18}\text{O}$  changes represent salinity changes of 2.9‰ and 5.6‰ for the western and eastern Mediterranean, respectively (Table 2b). Using the salinities determined for 18,000 yr BP, we estimate that salinities at 8,000 yr BP were ~36.5‰ in the western basin and 35.9‰ in the eastern basin.

TABLE 2 Oxygen isotope and salinity changes in the Mediterranean

a. Mean planktonic foraminifera			
Time interval	Western basin*	Eastern basin*	
18,000 yr BP-present	2.9‰	3.1‰	
18,000 yr BP-8,000 yr BP	3.6‰	4.3‰	
8,000 yr BP-present	-0.8‰	-1.2‰	

b. Oxygen isotope changes attributed to salinity and estimated salinity changes ( $\Delta S$ )				
Time interval	Western basin		Eastern basin	
	$\delta^{18}\text{O}$ (‰)	$\Delta S$ (‰)†	$\delta^{18}\text{O}$ (‰)	$\Delta S$ (‰)†
18,000 yr BP-present	0.5	1.2	1.1	2.7
18,000 yr BP-8,000 yr BP	1.2	2.9	2.3	5.6
8,000 yr BP-present	-0.8	-1.9	-1.2	-2.9

\* Based on data in Table 1.

† Derived from the seawater oxygen isotope/salinity relationship for the Mediterranean<sup>26</sup> whereby a 1.0‰ change in salinity produces a 0.41‰ change in  $\delta^{18}\text{O}$ .

As previously discussed, all of the observed  $\delta^{18}\text{O}$  change between 8,000 yr BP and the present can be attributed to salinity. The -0.8‰ and -1.2‰  $\delta^{18}\text{O}$  changes for the western and eastern basins (Table 2b) are equivalent to salinity increases of 1.9‰ in the western basin and 2.9‰ in the eastern basin between 8,000 yr BP and the present.

The estimated salinity changes have a number of important implications for both the palaeohydrographic and depositional conditions in the Mediterranean since the last glacial period. The present arid conditions in the Mediterranean region create a negative water balance (in that evaporation exceeds precipitation and runoff) which results in an anti-estuarine exchange with the North Atlantic (Fig. 2a). Our isotopic results indicate that these conditions changed during the last glacial (Fig. 2c). The higher glacial salinities suggest that the water balance of the Mediterranean became more negative as the region became even more arid than at present. This is in agreement with pollen and lake-level records from the circum-Mediterranean. In particular, African lake levels were at a minimum during the last glacial<sup>28</sup> and pollen spectra indicate colder, drier conditions between 26,000 and 13,000 yr BP than today<sup>29</sup>.

The isotopic evidence suggests that the west-to-east gradient in surface salinities was maintained during the last glacial, implying that surface and deep-water exchanges were similar to those of today (Fig. 2c). The Mediterranean was still exporting dense outflow water to the Atlantic during the last glacial<sup>30</sup>, although the volume of outflow was considerably reduced due to eustatically controlled restriction at the Gibraltar sill<sup>26</sup>. The salinity and density of glacial intermediate and deep waters in the Mediterranean would also have been elevated, because the sources of these water masses are simply Mediterranean surface waters. Because oxygen solubility decreases with increasing salinity, glacial deep waters in the Mediterranean probably had lower dissolved oxygen concentrations than at present.

Hydrographic conditions in the Mediterranean at 8,000 yr BP must have been considerably different than at 18,000 yr BP. The water balance became positive as precipitation and run-off exceeded evaporation (Fig. 2b). Salinities were considerably lower at 8,000 yr BP and the west-east salinity gradient was reversed to an east-west gradient. This is supported by East African climate records which indicate the onset of very humid conditions at ~12,500 yr BP, with wettest conditions occurring between 10,000-8,000 yr BP (refs 14, 28). This was also a time of intensified African monsoons and increased Nile discharge<sup>14,31</sup>.

The reversal of the salinity gradient coupled with a positive water balance in the Mediterranean at 8,000 yr BP strongly suggests a reversal of the surface flow patterns, that is, surface waters flowed out of the Mediterranean (Fig. 2b). This reversal

FIG. 1 Generalized planktonic foraminiferal oxygen isotope records for the western and eastern Mediterranean. The magnitudes of the isotopic differences between (1) 18,000 yr BP-present, (2) 18,000 yr BP-8,000 yr BP, and (3) 8,000 yr BP-present are indicated on each record.

of circulation patterns, previously proposed on the basis of sedimentological results<sup>32</sup>, may have begun as early as 12,000 yr BP with the onset of pluvial conditions in this region. Such a circulation change means that the Mediterranean was not a source of dense outflow to the Atlantic at this time.

As previously mentioned, 8,000 yr BP represents the midpoint of the deposition of the most recent sapropel (7,000–9,000 yr BP)<sup>18</sup>. Most workers have invoked versions of two general models for sapropel formation: a 'density-stratification' model and a 'productivity' model. The density-stratification model requires a low-salinity surface layer which inhibits bottom-water oxygen renewal and eventually results in anoxia<sup>33</sup>. The productivity model simply requires a high organic-carbon flux to produce sapropels<sup>18,34</sup>. Jenkins and Williams<sup>4</sup> and Howell and Thunell<sup>35</sup> evaluated both of these models and concluded that both increased productivity and a cessation of bottom-water renewal were required in order for sapropel deposition to occur within a period of several thousand years.

We believe that the key to understanding the formation of the most recent sapropel in the eastern basin is the glacial  $\delta^{18}\text{O}$  patterns in both basins. The  $\delta^{18}\text{O}$  patterns strongly suggest that high salinities (surface and deep water) during the last glacial were an important factor in 'preconditioning' the Mediterranean for sapropel deposition. First, bottom-water oxygen concentrations would have already been reduced because of the decrease in oxygen solubility associated with the increase in salinity. Second, the very high salinities which existed before sapropel formation would have more easily allowed the establishment of a density stratification with the onset of pluvial conditions. In addition, the circulation reversal would have caused the eastern Mediterranean to become a nutrient trap, thus enhancing pro-

ductivity. The combined effects of these conditions explains the most recent sapropel formation in the eastern Mediterranean and the contemporaneous deposition of reduced but not anoxic hemipelagic sediments in the western Mediterranean<sup>36</sup>.

THE volcanogenic massive sulphide deposits of the Hokuroko district of Japan are Miocene metal occurrences which are rich in both Zn and Pb, contain minor Cu and yield noteworthy amounts of Ag and Au (ref. 1). They formed in the Green Tuff belt of Japan in association with the felsic calc-alkaline rocks of a back-arc spreading centre<sup>1</sup>. Until now no modern analogue of this

FIG. 2 Cross-sectional views of the Mediterranean showing estimated surface salinities, water balance and inferred circulation patterns for a the present; b, 8,000 yr BP, and c 18,000 yr BP. Here, E, P and R denote evaporation, precipitation and runoff.

'Kuroko' type of sulphide deposit has been identified; this is in contrast to the Cyprus type of massive Cu-Zn sulphide deposit, which has such an analogue in the 'smoker' deposits of the East Pacific Rise. In 1984 and 1986, low-temperature oxide and silicate precipitates were discovered in the rift valley of the Okinawa Trough attesting to the recent occurrence of hydrothermal activity in this intracontinental back-arc basin<sup>2</sup>. On 26 June 1988, a large hydrothermal field with extensive occurrences of sulphide mineralization (the Jade hydrothermal field) was discovered and sampled by the German research vessel *Sonne* in a cauldron in the central part of the Okinawa Trough. Here we report geochemical and isotopic results which suggest that the Jade deposit is a modern analogue of the Kuroko-type deposits known so far only from the geological record.

The Okinawa Trough, located between the Ryukyu island chain and the east coast of China, is an active back-arc basin formed by extension within the continental lithosphere behind the Ryukyu trench-arc system. Evidence for the presence of active back-arc spreading exists only in the southern trough, whereas the main part of the graben system, characterized by normal faulting and crustal extension, is considered to be in the rifting phase<sup>3</sup>. The Middle Okinawa Trough probably represents a transition from present-day arc volcanism to volcanism associated with back-arc spreading. The local sea-floor map shows a series of parallel elongated ridges with 70° ENE strike, whereas the major structural grain is about 35° E which is indicative of a shear component in the deformation of the Middle Okinawa Trough. The ridges are composed of a bimodal assemblage of young volcanic rocks: basalt, andesite, dacite and rhyolite. First analyses made on board show that, according to their major-element geochemistry<sup>4</sup>, all the rock samples are of calc-alkaline island-arc type. The valleys and ridges are cut by normal faulting, giving rise to younger volcanic intrusions. Thus it is evident that the Okinawa Trough is a thermally active area<sup>5,6</sup> in which magma supply systems and extension processes create hydrothermal circulation.

The Jade hydrothermal field was discovered in a caldera-like structure (the Izena Cauldron<sup>7</sup>) which has a diameter of about 5 km. It is located at about 27°15.0' N and 127°04.5' E and lies 36 km south of the deposit from the hydrothermal mounds (Fig. 1a). The central part of the cauldron, which has a maximum water depth of about 1,650 m, is filled with younger, unconsolidated sediments at least 10–20 m thick according to our 3.5-kHz record<sup>4</sup>. Preliminary results show that heat flow at the bottom of the cauldron is high and variable, which indicates that hydrothermal circulation is probably taking place. The measured heat flow ranges from 100 to 800 mW m<sup>-2</sup> and increases somewhat towards the north (Fig. 1b). By following this gradient, we discovered the hydrothermal vent area in the northern part of the inside north-east slope (Fig. 1b) by instrumented deep tow using the Ocean-Floor Observation System. Two photographic, temperature and television profiles were carried out across the vent area; temperature measurements showed anomalies of up to ~0.5 °C (Fig. 1b). The local topography of the Jade field is generally rugged with small step-fault features resulting from the intense tectonics within the inner cauldron slope. Animals typical of the hydrothermal-vent communities on the East Pacific Rise<sup>8</sup>, such as white clams, galatheid crabs and lugworms, as well as white starfish, are observed in our deep-sea pictures.

Distinct signals in the water column can be used to identify active hydrothermal-vent areas. Methane contents ranging from ~5.4 to ~6.2 p.p.m. were measured in water between 1,400 and 1,420 m above the hydrothermal field, at a total depth of 1,480 m. The Mn concentration measured above the vent area in the same depth range is ~2–3 parts per 10<sup>9</sup> (p.p.b.) (measured background values of Mn varied between 0.2 and 0.3 p.p.b.). In the central part of the cauldron basin, concentrations as high as 8.8 p.p.m. CH<sub>4</sub> were measured at a depth of about 1,600 m; the CH<sub>4</sub> background in the surroundings of the cauldron is 0.02–0.05 p.p.m. These high CH<sub>4</sub> and Mn concentrations reveal

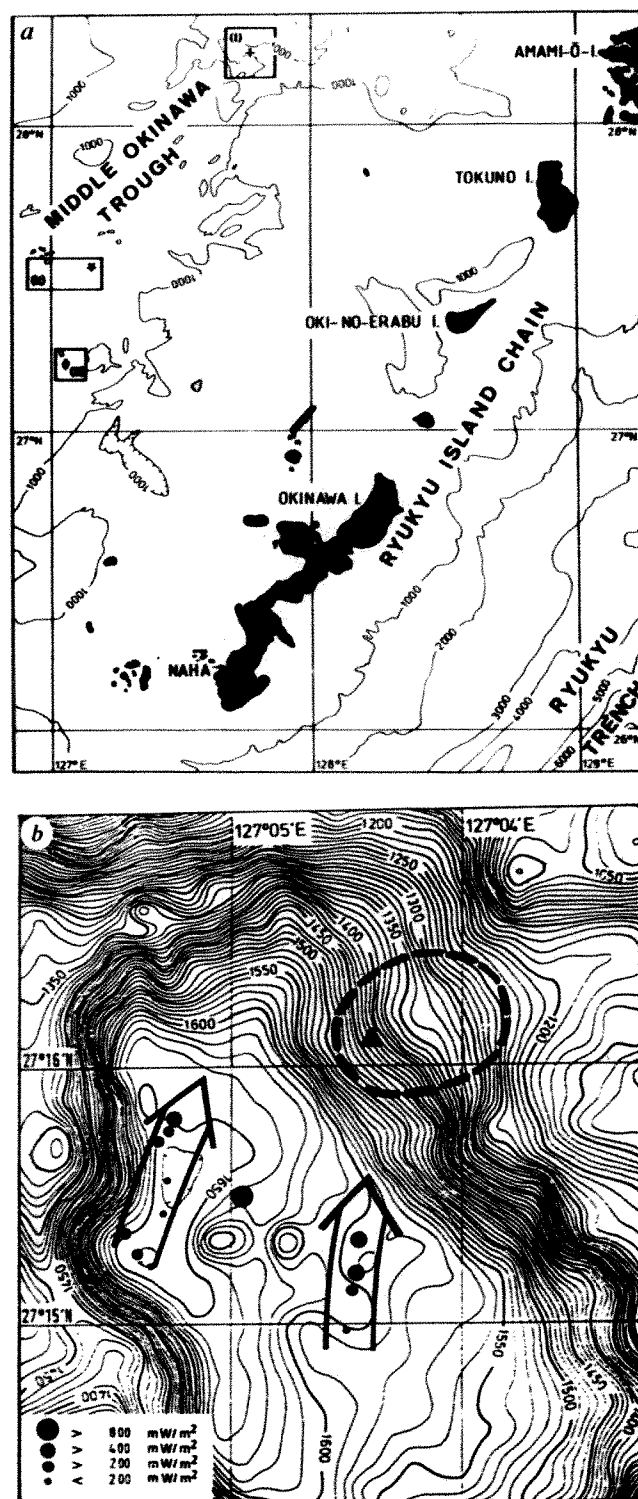

FIG. 1 Location maps for hydrothermal vents in the Okinawa Trough. a, Map<sup>15</sup> of the central part of the Ryukyu trench-arc system, which is located between the island of Kyushu in the north-east and the island of Taiwan in the south-west. A section of the Middle Okinawa Trough is also shown. The areas (I), (II) and (III) were studied during the research cruise S0 56. + and ★ indicate locations of oxidic-siliceous low-temperature hydrothermal-mound deposits, ◆ shows the location of the Izena Cauldron with the Jade Hydrothermal Field. b, Part of the bathymetric map of the Izena Cauldron (location (III) in a). The Jade deposit lies on the inside north-east slope and is delimited by the dashed line. The contour interval of water depth is 10 m. ▲ marks the spot of the temperature anomaly (~0.5 °C) measured about 5 m above the bottom, which indicates hydrothermal venting. The two arrows show the approximate trend of increasing heat flow within the sediments of the basin, based on heat-flow data measured during the S0 56 cruise. The dots indicate heat-flow values.

the existence of a strong hydrothermal plume, which seems to be particularly pronounced because of the protected environment in the caldera.

We identified four different varieties of sea-bed sulphide mineralizations in the dredged material, namely two types of massive sulphides, a stockwork mineralization and a sulphide-bearing sediment layer. We now describe each of these in detail. (1) The first massive sulphide (MS I) comprised black-grey fragments of stacks, which accumulate around and on the hydrothermal vents by direct accretion of minerals precipitated from the hydrothermal fluid. Initial microscopic studies of the ore reveal that they represent a late stage of low-temperature hydrothermal activity. The youngest minerals in the outer layer (0–2 cm thick; Table 1, column A) are barite, realgar, orpiment, amorphous silica and millimetre-thick surface coatings of hydrous iron-manganese oxides. Other sulphide minerals are sphalerite (including schalenblende), Ag-bearing galena and pyrite (Table 1). The central parts (at 4–6 cm depth; Table 1, column C) consist mainly of the three sulphide minerals above; some chalcopyrite is present, but mostly as myrmekitic inclusions or as fine-grained replacement textures described as 'chalcopyrite disease'. The barite and amorphous-silica content is significantly lower than in outer layers, and arsenic minerals are rarer.

(2) The second type of polymetallic sulphide (MS II) is olive-green to grey. The recovered material consists of elongated plates, several centimetres in thickness, which show a very fine and porous structure. The main minerals are sphalerite, chalcopyrite and pyrite, accompanied by anglesite and lesser amounts of amorphous silica. The higher concentration of chalcopyrite and the lack of galena probably indicates a higher primary temperature of formation relative to the MS I type. Anglesite was probably formed at higher oxygen fugacity than were the sulphides. Replacement of previously formed galena by anglesite was not observed.

(3) Within the host rocks of hydrothermally altered rhyolite are found millimetre-thick fracture fillings of stockwork mineralizations. These minerals are sphalerite, tennantite (Ag- and Sb-bearing), galena, enargite and, to a lesser extent, pyrite and chalcopyrite. The altered rhyolite consists of an extremely fine-

grained mixture of quartz, muscovite and some feldspar. Besides the fracture fillings, replacement masses are observed which contain basically the same sulphide minerals but with coarser grain-sizes. In some cracks of both the stockwork mineralization and the MS I type samples, millimetre-thick precipitates of native sulphur occur. Native sulphur is in general an oxidation product of  $H_2S$ . Its occurrence therefore indicates that in the venting hydrothermal fluid the concentration of  $H_2S$  was high and contributed to the formation of native sulphur after precipitation of the prevailing sulphide assemblage.

(4) Within two cores taken from the north-eastern part of the caldera basin, a sulphide-bearing layer of 10–15 cm in thickness was observed at a depth of about 80 cm below the top of the sediment. The fine-grained, unconsolidated, greyish material contains considerable amounts of sphalerite, pyrite and barite; the detrital minerals are quartz, calcite, illite and chlorite. As the sulphide-bearing sediment layer could not be observed in cores from the western part of the caldera basin, we suggest that the sulphide minerals were supplied from the Jade hydrothermal field.

Microthermometric data may be used to estimate mineral formation temperatures and salt concentrations of hydrothermal fluids. Such measurements have been conducted in the outer Ba- and As-rich material (sample A in Table 1) of the MS I type mineralizations. Each of the barite grains was found to be water-clear. The fluid inclusions have average lengths of 5–6  $\mu m$  and are not bound to any cleavage. The nine measurements yielded fairly constant temperatures of homogenization of  $160 \pm 5^\circ C$ . The salt content of the fluid inclusions is somewhat higher than in normal ocean water (freezing temperature  $-1.9^\circ C$ ), as indicated by freezing-point depressions ranging from  $-2.8$  to  $-3.4^\circ C$ . Thus, this barite was formed at about  $160^\circ C$ , probably through mixing of Ba-bearing hydrothermal solution with cold sulphate-rich sea water.

Chemical metal analyses (Table 1) indicate that the Jade massive sulphides are particularly rich in Zn and Pb but contain only minor amounts of Cu, with the exception of samples E (stockwork mineralization) and F (MS II type); samples A to D (MS I type) also exhibit significant Ag and Au content, with the Au/Ag ratio varying between 0.001 and 0.02, which is in the same range as values for other sea-floor massive sulphide deposits<sup>10</sup>. Point measurements, made by electron microprobe analysis, of galena grains in samples B and C revealed an Ag content of  $0.28 \pm 0.06\%$  (32 measurements). Thus, in addition to tennantite, galena is an important host phase of Ag. No Ag was, however, detected in sphalerite.

In comparison with other recent sea-floor sulphide deposits<sup>10,11</sup> the Ag concentration of 0.65% and the Au content of 9.8 p.p.m. (Table 1) are the highest found so far. Concentrations of Ba and As are found to be greatest in the upper 2 cm (Table 1, column A) of the MS I stack samples, indicating that barite, realgar and orpiment formed in the cooler and more oxidizing parts of the hydrothermal system. Au is related to these late precipitates; maximum concentrations of Ag occur more towards the inner parts (Table 1, columns B, C).

Au occurs at minor concentrations (0.3–0.7 p.p.m.; Table 1) in the chalcopyrite-rich samples of the MS II type and stockwork mineralizations, but is enriched by about one order of magnitude in the late paragenetic sulphide-sulphate-silica mineral system. Thus it is reasonable to assume that a remobilization of Au from the earlier, high-temperature sulphides has taken place, followed by reconcentration of Au in the more oxidized outer portions of the deposit through sustained hydrothermal circulation. Late, lower-temperature ( $<250^\circ C$ )<sup>11</sup> solutions ascending through massive sulphides would remove Au as the bisulphide complex  $(Au(HS)_2^-)$  because of the high concentration of sulphur. Mixing with cooler sea water would result in a decrease in the solubility of Au, particularly below  $200^\circ C$  (ref. 10). The chloride complex  $(AuCl_2^-)$  is more important in early, high-temperature ( $300$ – $400^\circ C$ ) solutions<sup>10</sup> and might account for the high Au content

§ Olive green MS II type sample.

in the more Cu-rich sulphide samples.

The sulphur isotope values  $\delta^{34}\text{S}$  (‰ relative to CDT standard) of 17 pyrite samples from MS I type ores range from +4.3 to +10.7‰, being generally between +6 and +8‰. Values from barite lie within the range +21.9 to +23.6‰. The Jade pyrites have substantially higher  $\delta^{34}\text{S}$  values than other recent sea-floor sulphide deposits at mid-ocean ridges<sup>12,13</sup>, being comparable with Kuroko sulphides, which have  $\delta^{34}\text{S}$  values ranging from +5 to +8‰ (ref. 14). The Jade barites are isotopically similar to other barites, implying a seawater-sulphate origin ( $\delta^{34}\text{S}$  values of modern sea water: +20.3‰).

The Hokuroku district in northern Honshu is the type locality of the Kuroko massive sulphide occurrences, which are found in association with felsic calc-alkaline volcanic rocks<sup>1</sup>. The latter consist of rhyolite and dacite, which intruded to shallow depths below the sea floor or poured out on the sea bottom. They generally underlie stratiform ore bodies, but may also serve as host rocks for stockwork mineralizations. In Kuroko deposits, Au-rich black ores are found stratigraphically above Au-poor, higher-temperature yellow ores and stockwork mineralizations<sup>11</sup>. Our results suggest that the Jade hydrothermal field is analogous, in its nascent state, to the volcanogenic Kuroko-type massive sulphides. □

**ACKNOWLEDGEMENTS.** The cruise SO 56 was staged by the German-Japanese joint project to study hydrothermal activity in the Okinawa Trough. We thank the crew members and all scientists who participated. The research project was supported by a grant from the German Federal Ministry for Research and Technology. We thank Dr T. Moritani for his help, the Japanese Ministry for Foreign Affairs for the permission to work within the Japanese EEZ, and the Japanese Hydrographic Department for providing unpublished sea-floor maps. Dr Hein assisted in investigating the fluid inclusions and E. Riessen carried out part of the metal analyses. Dr F. Yanagisawa determined the  $\delta^{34}\text{S}$  values reported here.

## Microbial biomass acts as a source of plant nutrients in dry tropical forest and savanna

J. S. Singh, A. S. Raghubanshi, R. S. Singh & S. C. Srivastava

Department of Botany, Banaras Hindu University, Varanasi 221005, India

**MORE than half of all tropical soils are highly weathered, leached and impoverished, requiring the ecosystem to develop nutrient-conserving mechanisms<sup>1,2</sup>. Nutrient retention and withdrawal mechanisms are most effective in nutrient-poor systems<sup>3,4</sup>. Thus, although dry tropical forests and savanna have the potential capacity to grow at high rates<sup>5,6</sup>, this capacity is strictly limited by climate and nutrients. Our studies on these nutrient-poor ecosystems show that a reciprocal relationship exists between microbial biomass and plant growth rate. This suggests that microbial immobilization may be a main source of nutrients for the plants and may lead to nutrient conservation.**

To study the factors affecting plant growth in nutrient-poor ecosystems, we selected sites in the Vindhyan hill tract (24°20'–25°10' N and 82°30'–83°30' E) of India. The soils at these sites are ultisols, derived from Kaimur sandstones (Dhandraul orthoquartzite). They are reddish brown in colour, sandy loam in texture<sup>6–7</sup>, shallow, leached, and have moderate water-holding capacity (30–50%). The annual rainfall averages 800 mm, of which more than 75% is received during the monsoon season (late June to early September). November to February is a cool dry period (winter) and March to mid-June is hot and dry (summer). Although leaf emergence in most woody species precedes the rainy season, perhaps supported by nutrients withdrawn from senescing leaves, massive biomass accretion coincides with the growth spurt of the herbaceous layer triggered by the first showers of monsoon rain<sup>8</sup>. The herbs start drying up from October, leaving a substantial amount of their roots in the soil.

Every month five samples were collected from the upper 10-cm layers of soil at each site. Ammonium-N and nitrate-N were determined by the phenate and phenol-disulphonic acid methods, respectively, and phosphate-P was determined by the molybdate blue method<sup>9–11</sup>. An *in situ* incubation technique was used to measure nitrification<sup>12</sup>. Microbial C was determined using a modified liquid chloroform fumigation incubation technique, and microbial N and P were determined using fumigation extraction method<sup>13–15</sup>.

The contents of extractable ammonium-N and phosphate-P were low and varied considerably within the annual cycle. In forest soils, nitrate-N varied from 0.4–5.6 µg per g dry soil, and in savanna soils from 0.4–0.8 µg per g. Values for ammonium-N were in the ranges 1.2–4.0 and 2.0–5.0 µg per g for forest and savanna sites, respectively. The contents of phosphate-P extracted using NaHCO<sub>3</sub> varied from 1.4–4.8 µg per g for forest soils and from 2.0–4.0 µg per g for savanna soils; the highest levels of phosphate-P as well as inorganic-N occurred in the summer. There was a marked seasonality in the rate of nitrification which peaked during the rainy season (Fig. 1); all soils showed little or no net nitrification during the dry period. The peak nitrate production rates in these ecosystems were lower than the minimum rates reported for tropical rain forest sites in Brazil, Costa Rica and Panama<sup>16</sup>. Low nutrient pools and low rates of nitrification show that these systems are extremely nutrient poor.

The highest and lowest levels of microbial biomass N occurred in the summer and rainy season, respectively, and the range of

FIG. 1 Nitrification in dry tropical forest and savanna sites. ●—●, Forest; ○—○, grass savanna and ○—○, bamboo savanna (bars, 1 s.e.).

TABLE 1 Microbial biomass C, N and P in dry tropical ecosystems

Season	C	N	P
Forest			
Rainy	487 ± 9.2	51 ± 0.3	20 ± 1.7
Winter	662 ± 14.8	70 ± 1.2	29 ± 3.3
Summer	744 ± 10.3	88 ± 4.1	31 ± 1.6
Savanna			
Rainy	262 ± 7.5	31 ± 0.2	11 ± 1.5
Winter	400 ± 7.5	32 ± 0.7	19 ± 1.6
Summer	520 ± 9.4	46 ± 1.7	23 ± 1.8

Biomass C, N and P contents given as  $\mu\text{g g}^{-1}$  dry soil. Differences due to seasons were significant at  $P < 0.001$  for both the forest and savanna ecosystems.

values measured (31–88  $\mu\text{g per g}$ ) fell within that reported for the Amazonian rain forest sites<sup>17</sup>. Microbial immobilization of  $^{15}\text{N}$  is reported to be greater at sites where the rates of nitrification are low than at sites where they are high<sup>16</sup>. Furthermore, the activity of soil microbes is less sensitive to soil water potential than is water uptake by the plants<sup>18–19</sup>, and it is possible that a substantial amount of water is present at high tension during summer which is unavailable to plants but available to microbes<sup>1</sup>. It seems, therefore, that microbial activity in these systems continues during dry months but that plant growth is drastically reduced, curtailing the demand for nutrients. Mineralization products and nutrients that move upward through capillary action in the dry season are thus immobilized in the microbial biomass.

In the ecosystems studied the microbial biomass and nutrient pools declined as N-mineralization increased, during the period when plant growth was most rapid. This correlation indicates that N immobilized in microbes is an important source of N for plants. This contrasts with the common assumption that steady-state mineralization is responsible for most of the nutrient supply to plants. Accelerated pulsed turnover of microbes in the rainy season may result from grazing by soil animals such as protozoa and nematodes. The populations of protozoa, fungivorous microarthropods and bacteria- and fungi-vorous nematodes expand in this season<sup>20–22</sup>. Grazing of bacteria is necessary to make nutrients available for plant uptake<sup>23–24</sup>. Mineral N is released mainly from dead microbial cells, microbial materials and microbial metabolites<sup>25</sup>. Fresh plant material has to be partly humidified before mineral N might be released<sup>26</sup>. The turnover of N from dead microbial cells is about five times that from native soil organic N<sup>27–28</sup>. In low-N soils, microbial biomass is as effective as nitrate-N in supplying N to wheat<sup>29</sup>. Vitousek and Matson<sup>30</sup> have concluded that microbial biomass, if conserved during forest management, retains N in harvested loblolly pine plantations.

We conclude that microbial biomass in these nutrient-poor systems acts as a sink and a source of nutrients. The principal function of the microbial biomass is thus to accumulate and conserve nutrients in a biologically active form during the dry period (high biomass, low turnover), when the activity of the plants is low and they are not able to extract nutrients effectively from soil, and then to release them rapidly during the monsoon period (low biomass, high turnover) to initiate plant growth. □

## Temporally distinct pre- and post-synaptic mechanisms maintain long-term potentiation

Stephen N. Davies, Robin A. J. Lester\*, Klaus G. Reymann† & Graham L. Collingridge

Department of Pharmacology, University of Bristol, School of Medical Sciences, University Walk, Bristol BS8 1TD, UK

LONG-TERM potentiation (LTP) in the hippocampus is widely studied as the mechanisms involved in its induction and maintenance are believed to underlie fundamental properties of learning and memory in vertebrates<sup>1</sup>. Most synapses that exhibit LTP use an excitatory amino-acid neurotransmitter that acts on two types of receptor, the N-methyl-D-aspartate (NMDA) and quisqualate receptors<sup>2</sup>. The quisqualate receptor mediates the fast synaptic response evoked by low-frequency stimulation<sup>3,4</sup>, whereas the NMDA receptor system is activated transiently by tetanic stimulation, leading to the induction of LTP<sup>3,5–7</sup>. The events responsible for maintaining LTP once it is established are not known. We now demonstrate that the sensitivity of CA1 neurons in hippocampal slices to ionophoretically-applied quisqualate receptor ligands slowly increases following the induction of LTP. This provides direct evidence for a functional post-synaptic change and suggests that pre-synaptic mechanisms also contribute, but in a temporally distinct manner, to the maintenance of LTP.

The excitatory post-synaptic potential (e.p.s.p.) evoked in CA1 neurons by low frequency stimulation of the Schaffer collateral-commissural pathway (see Fig. 1a) is depressed by the quisqualate antagonist 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX)<sup>4,8–10</sup>. In physiological medium, NMDA antagonists do not affect this e.p.s.p. either before or after the induction of LTP<sup>3</sup>; it is therefore assumed that the potentiated e.p.s.p. is mediated by quisqualate receptors. To test this directly, we compared the sensitivity to CNQX of potentiated and unpotentiated inputs onto the same population of CA1 neurons. As illustrated in Fig. 1, 10  $\mu\text{M}$  CNQX, a concentration that depresses responses of CA1 neurons to quisqualate and AMPA

\* Present address: Vollum Institute for Advanced Biomedical Research, 3181 S.W. Sam Jackson Park Road, Portland, Oregon 97201, USA.

but not NMDA<sup>4</sup>, depressed both inputs in parallel ( $n = 6$ ). Thus, the receptors that mediate the potentiated response are probably of the quisqualate receptor subtype. This result means that if LTP is maintained by post-synaptic mechanisms there should be an associated increase in the sensitivity of neurons to appropriately administered quisqualate receptor ligands.

To test for this, intracellular recordings were obtained from CA1 pyramidal neurons (Fig. 2). In five cells, tetanic stimulation elicited immediate and stable LTP; the respective mean ( $\pm$ s.e.m.) amplitudes of the e.p.s.p., measured from averages of 10 successive responses, 0–5 min before and 25–30 min after the induction of LTP were  $5.3 \pm 0.8$  and  $8.5 \pm 1.3$  mV (mean increase,  $53 \pm 12\%$ ). The generation of LTP was not associated with any significant change in either the resting membrane potential or resting input resistance; the values at the corresponding times were  $-69 \pm 2$  and  $-70 \pm 2$  mV, and  $29 \pm 2$  and  $31 \pm 3$  M $\Omega$ , respectively. In these cells, quisqualate elicited depolarizations of  $5.7 \pm 0.7$  mV, measured from averages of 10 successive responses 0–5 min before the induction of LTP. By contrast with the synaptic response, quisqualate-induced depolarizations were not immediately affected by tetanic stimulation. For example, the mean depolarization 5–10 min after the induction of LTP was still  $5.7 \pm 0.7$  mV. Thereafter, however, there was a tendency for the quisqualate-induced responses to increase in size. In four cells there was an increase ( $21 \pm 6\%$ ) by 25–30 min post-tetanus and in the fifth cell the response size showed a comparable increase by 60 min. By contrast, in three cells tetanic stimulation resulted in neither the generation of LTP nor an increase in sensitivity to quisqualate. Thus, in only those cells where stable LTP had been induced was there a delayed increase in sensitivity to quisqualate.

To quantify the effect further, stable extracellular d.c. potentials<sup>11</sup> were obtained in response to ionophoretic administration of the selective quisqualate receptor agonist AMPA ( $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazole propionic acid) at 15-min intervals for 1 h before and 3 h following tetanic stimulation (Fig. 3). In control medium this elicited LTP in 9 out of 11 slices;

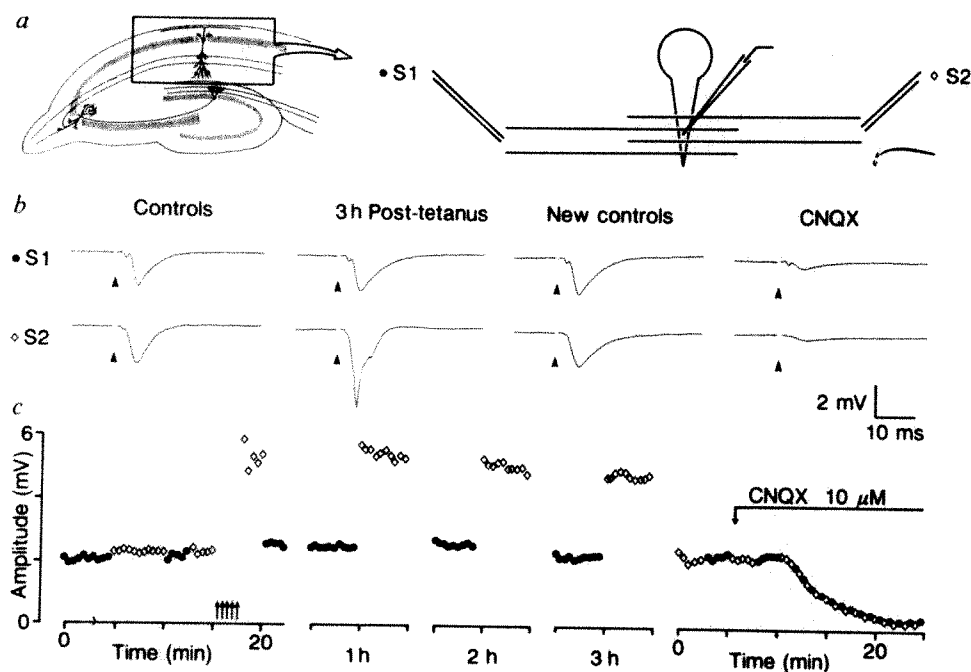

the mean change in the field e.p.s.p. amplitude (and slope) 2 h after the tetanus for all 11 slices was  $+47 \pm 21\%$  ( $+82 \pm 34\%$ ) of control. Usually the sensitivity of the cells to the first post-tetanus AMPA application was unaltered. In most cases, however, the sensitivity to AMPA then gradually increased, reaching a maximum after about 2 h and persisting throughout the 3-h period following the tetanus. The mean change for all 11 slices at 2 h was  $+62 \pm 25\%$  ( $P < 0.05$ ; paired  $t$ -test).

If the change in AMPA sensitivity is the result of the generation of LTP, it should be blocked by treatments that prevent the induction of LTP, such as adding an NMDA antagonist<sup>3</sup>. In the presence of  $50 \mu\text{M}$  D-2-amino-5-phosphonovalerate (APV) there was neither the production of LTP (mean change in field e.p.s.p. 2 h after tetanus was  $-9 \pm 9\%$  ( $-2 \pm 8\%$ ) of control), nor any consistent change in the sensitivity of CA1 neurons to AMPA (Fig. 3). The mean change in the amplitude of the AMPA responses 2 h post-tetanus was  $-7 \pm 12\%$  ( $P > 0.05$ ; paired  $t$ -test). In three slices, tetanic stimulation was delivered first in the presence of APV and, 3 h later, after washout of APV; invariably APV reversibly prevented both the induction of LTP and the sensitivity change to AMPA (Fig. 3).

To examine whether the potentiated AMPA response involved activation of local synaptic circuitry, we tested the effects of a  $\text{Ca}^{2+}$ -channel antagonist on responses 2 h after tetanization. In these slices, synaptic and AMPA-induced responses had increased 2 h post-tetanus by  $33 \pm 7\%$  ( $62 \pm 15\%$ ) and  $43 \pm 8\%$  ( $n = 4$ ), respectively. Cadmium ( $50$ – $100 \mu\text{M}$ ) reduced the amplitude of the synaptic response by  $56$ – $70\%$  but had no effect on the amplitude of the AMPA-evoked depolarizations.

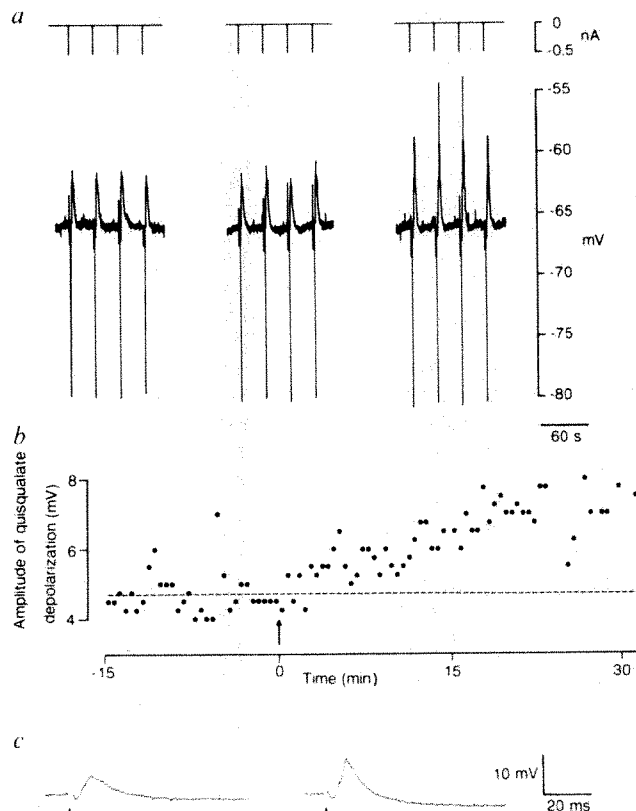

Whether LTP is maintained by pre-synaptic<sup>12–14</sup> or post-synaptic<sup>15–17</sup> mechanisms is controversial. Our data suggest that in the Schaffer collateral-commissural pathway both mechanisms occur but with different time courses. Previous studies have failed to detect an increase in sensitivity to ionophoretically administered agonists with LTP<sup>18–20</sup>. There are two explanations for this. First, the sensitivity to exogenously applied agonists was followed only for short periods and, as we show, sensitivity

FIG. 1 CNQX blocks in parallel potentiated and unpotentiated field e.p.s.p.s. a, Diagrammatic representation of the recording arrangement for this series of experiments; an extracellular recording electrode was placed in stratum radiatum of area CA1 and two stimulating electrodes (S1 and S2) were positioned  $\sim 1$  mm on either side. A large separation was used to minimize the current to which both electrodes stimulated the same fibres. LTP was induced by stimulating one input using five trains delivered at 30-s intervals. Each train comprised 100-Hz stimulation for 1 s at double test intensity. After the induction of LTP (15, 30 or 180 min) the amplitude of the two inputs was matched by increasing the stimulus intensity of the control input or by decreasing that of the potentiated input and CNQX was then applied. b, An example from one slice of field e.p.s.p.s. evoked by the two stimulating electrodes showing from left to right, matched control responses (2.8 and 3.0 V), responses after tetanization of S2, new matched controls after S2 intensity had been reduced to 2.1 V, and finally the effect of CNQX ( $10 \mu\text{M}$ ) on the two responses. In these and subsequent figures synaptic records are averages of 3–10 consecutive responses and the position of the blanked stimulus artefacts are indicated by arrowheads. The time of tetanization is shown by arrows. c, Amplitude of the field e.p.s.p.s. plotted throughout the experiment illustrated in b showing the parallel reduction by CNQX of the potentiated and the unpotentiated response.

METHODS. Rat hippocampal slices ( $400\text{-}\mu\text{m}$  thick) were prepared and maintained in an interface type chamber at  $30$ – $32^\circ\text{C}$ , using standard techniques<sup>3</sup>. They were perfused with medium containing: NaCl,  $124$  mM; KCl,  $3$  mM;  $\text{NaHCO}_3$ ,  $26$  mM;  $\text{CaCl}_2$ ,  $2$  mM;  $\text{MgSO}_4$ ,  $1$  mM; D-glucose,  $10$  mM;  $\text{NaH}_2\text{PO}_4$ ,  $1.25$  mM (omitted for cadmium experiments), bubbled with a  $95\%$   $\text{O}_2/5\%$   $\text{CO}_2$  mixture.

changes are usually slow to develop. Second, L-glutamate was used which, unlike AMPA and quisqualate in hippocampal slices<sup>4</sup>, exerts only part of its action through CNQX-sensitive receptors<sup>21</sup>. Our results favour a pre-synaptic component to the early maintenance of LTP in the Schaffer collateral-commissural pathway because LTP was produced within 30 s, yet sensitivity changes were not usually detected for at least 15 min and took ~2 h to reach a maximum.

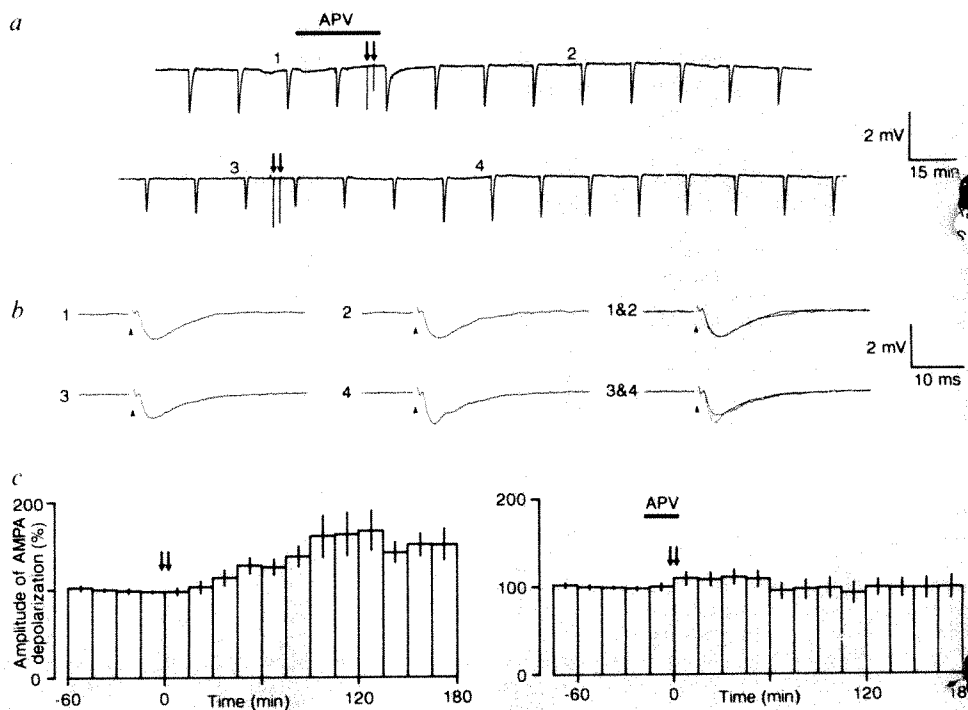

An intriguing feature of the post-synaptic change is its slow development. Interestingly, in the presence of protein kinase C (PKC) inhibitors, LTP lasts for only 1–2 h (refs 22–24); a time similar to that required for maximal potentiation of the AMPA-induced responses. Moreover, injection of purified PKC into the post-synaptic neuron induces an LTP-like change in synaptic transmission<sup>25</sup>. It is possible that PKC contributes to the initiation of this slowly developing, postsynaptically-located com-

FIG. 2 LTP is associated with a delayed increase in sensitivity of single CA1 neurons to quisqualate. *a*, Current (top) and voltage (bottom) records from an intracellularly recorded CA1 pyramidal neuron. Depolarizations are in response to ionophoretic ejection of quisqualate (130 nA, 2 s) into stratum radiatum. These are preceded by hyperpolarizations in response to constant current pulses (0.5 nA, 400 ms), used to monitor resting input resistance. Panels illustrate from left to right, control records, sections taken immediately after, and sections taken 30 min after the tetanus (100 Hz, 1 s, test intensity). Two of the last four quisqualate-induced responses depolarize the cell sufficiently to fire action potentials. *b*, Plot showing the amplitude of quisqualate-induced depolarizations for 15 min before and 30 min following the tetanus (arrow). Thereafter (for a further 45 min) quisqualate-induced depolarizations excited the cell sufficiently to elicit firing. *c*, Synaptic responses taken immediately before and 30 min after the tetanus.

**METHODS.** Intracellular recordings were obtained from the cell-body layer using electrodes containing 3 M potassium acetate and the Schaffer collateral-commissural pathway was stimulated at 30 s intervals by a single electrode placed in stratum radiatum. An ionophoretic pipette was positioned in stratum radiatum at the level of the stimulated fibres, adjacent to the recording site. Quisqualate (20 mM in 150 mM NaCl) was applied ionophoretically (46–163 nA, 1–2 s) 5 s after each synaptic response was elicited. The position of the ionophoretic pipette was adjusted to achieve a compromise between short latency responses (indicating that the pipette was close to a dendritic branch of the recorded cell) and the maintenance of stable recordings. Only those cells where passive membrane properties and both synaptic and agonist-induced responses remained stable for 15 min before tetanic stimulation (100 Hz, 1 s, test intensity) and where healthy impalements could be maintained for at least a further 30 min were included in the analysis.

FIG. 3 The delayed increase in sensitivity is dependent on the synaptic activation of NMDA receptors. *a*, d.c. potentials evoked in the stratum radiatum by ionophoretic ejection of AMPA (87 nA, 20 s) every 15 min. In the upper panel APV (50  $\mu$ M) was present during the tetani and there was minimal change in the size of the AMPA-induced responses. In the lower panel a second pair of tetani delivered 3 h later in the absence of APV induced a delayed increase in the amplitude of the AMPA-induced responses. The two sections of record are continuous. *b*, Field e.p.s.ps recorded at times indicated, showing synaptic responses before and 1 h after the tetani. *c*, Pooled data showing effect of tetanization on amplitude of AMPA responses (normalized to mean of control responses) in the absence ( $n=11$ ) and presence ( $n=8$ ) of APV (50  $\mu$ M). Error bars show  $\pm 1$  s.e.m.

**METHODS.** The experimental arrangement was similar to that shown in Fig. 1, except that the two stimulating electrodes were placed closer together to maximize the number of tetanized synapses in the vicinity of the recording electrode. Each pathway was tetanized once (100 Hz, 1 s, double test intensity). AMPA (20 mM in 150 mM NaCl) was applied ionophoretically

(40–155 nA, 10–25 s, at 15 min intervals) from a pipette close to the recording electrode.

ponent of LTP. The early presynaptic component presumably involves PKC-independent mechanisms. One possibility is that NMDA receptor activation releases arachidonic acid metabolites<sup>26</sup> from the post-synaptic cell and that these act as retrograde messengers which result in the enhanced neurotransmitter release<sup>27,28</sup>.

## Presentation of antigen, foreign major histocompatibility complex proteins and self by thymus cortical epithelium

Philippa Marrack\*†‡, James McCormack & John Kappler†‡

Howard Hughes Medical Institute, Department of Medicine, National Jewish Center for Immunology and Respiratory Medicine, and Departments of Biochemistry, Biophysics and Genetics\*, and Microbiology and Immunology†, and Medicine‡, University of Colorado, Denver, Colorado 80207, USA

IN mouse and man most peripheral T cells bear clonally variable receptors made up of  $\alpha$ - and  $\beta$ -chains<sup>1</sup> which bind ligands on target cells consisting of peptide fragments of foreign antigens, complexed with cell surface proteins encoded by the major histocompatibility complex (MHC) of the individual<sup>2–4</sup>. In the thymus, developing T cells are selected to mature only if their receptors will be able to participate in self-MHC plus antigen recognition in the periphery<sup>5–8</sup>. This positive selection occurs in the presence of self-MHC, but in the apparent absence of antigen, leading to the paradoxical conclusion that developing thymocytes must be positively selected by engagement of their receptors and self-MHC alone, although thymocytes that react too well with self-MHC are eliminated<sup>9</sup>. To account for this, it has been suggested that MHC molecules in the thymus are not identical to those found elsewhere<sup>1</sup>. To test this and other hypotheses, we have examined the ability of the presumed selecting cells, those of the thymus cortical epithelium<sup>10,11</sup>, to present various MHC complexes to T cells. Our results indicate that MHC molecules on thymus epithelium are not always the same as those found elsewhere.

Thymus cortical epithelial cells were isolated as nurse cells<sup>12</sup> from BALB/c (H-2<sup>d</sup>) mice and tested for their ability to present antigen plus I-A<sup>d</sup>, or I-E<sup>d</sup> to T-cell hybridomas. T-cell-depleted BALB/c spleen cells were used as controls. As shown in Fig. 1a and b, a T-cell hybridoma specific for I-E<sup>d</sup> as an alloantigen, CG4, responded equally well to the nurse cell and spleen cell preparations in the dose ranges tested. Similar results were obtained using a T-cell hybridoma from BALB/c mice, specific for a peptide of chicken ovalbumin (cOVA)/I-A<sup>d</sup>, 3DO-8.2 (Fig. 1c, d). Kyewski *et al.*<sup>13</sup> have previously shown that thymus epithelial cells cannot present antigen to T-cell clones. The discrepancy between their results and those shown here may be due to our use of T-cell hybridomas, cells which, unlike the normal T cells used by Kyewski *et al.*, require only  $\alpha/\beta$ -receptor engagement and no secondary signals to respond.

Our results show that some cells in the thymus epithelium preparation can present allogeneic MHC or antigen plus self-MHC to T-cell hybridomas. Although the active cells could be contaminant macrophages or dendritic cells, it seems that the epithelial cells themselves contribute to the presentation: not only did the nurse-cell preparations contain no or few rosette-forming dendritic cells or macrophages, but their antigen-presenting activity did not fall off upon selectively enriching for nurse cells (data not shown). Also, as shown below, the nurse cell preparations were selectively deficient in their ability to present antigen-MHC complexes which are expressed on B cells and macrophages *in vivo*.

Recently it has been shown that almost all T-cell receptors that include V $\beta$ 17a impose reactivity for IE plus a B-cell-derived product on T cells which bear them<sup>14,15</sup>. Despite this, V $\beta$ 17a<sup>+</sup> cells seem to react with I-E on macrophages isolated from mice, perhaps because of transfer of the B-cell-derived product from one cell to another *in vivo*. Indirect evidence, however, suggested that the V $\beta$ 17a ligand might not exist on selecting cells in the thymus, as V $\beta$ 17a<sup>+</sup> cells are not 'overselected' in thymuses which express I-E on thymus epithelium, but elsewhere<sup>16</sup>. To test this, three V $\beta$ 17a<sup>+</sup> T-cell hybridomas were challenged with I-E<sup>d</sup> on BALB/c nurse or spleen cells. The hybridomas responded poorly to nurse cells, and much better to spleen cells (Fig. 1e, f). This indicates that V $\beta$ 17a<sup>+</sup> T cells do not react well, if at all, with IE on thymus nurse cells, as the small responses seen against our epithelial cell preparations may have been against contaminating cells. Preliminary experiments show that nurse cells from transgenic mice, expressing I-E on only thymus epithelial cells, do stimulate weak responses from some V $\beta$ 17a<sup>+</sup> hybrids, indicating that the V $\beta$ 17a ligand might be present on thymus epithelium, albeit at low levels.

We also tested the ability of T-cell hybrids to react with syngeneic thymus epithelium in the absence of antigen. A BALB/c-derived T-cell hybridoma specific for cOVA/I-A<sup>d</sup>, 3DO-54.8, reacted with the BALB/c nurse cell preparation in the absence of antigen (Fig. 1g, h). This T cell did not react with spleen cells in the absence of cOVA, even when the spleen cells had been subjected to the same enzyme treatments as the nurse cells, nor did it react with BALB/c-derived, I-A<sup>d</sup>-bearing macrophages or B-cell lymphomas. The failure of 3DO-54.8 to react with spleen cells was not due to a splenic inhibitory activity, as mixtures of splenic and nurse cells stimulated this and another hybrid as well as the nurse cell preparations alone (data not shown).

Several independent T-cell hybridomas were tested for their ability to react with syngeneic nurse cells (Fig. 2). The BALB.B (H-2<sup>b</sup>)-derived hybridomas, BO-97.10 and 2BO-43 responded quite well to H-2<sup>b</sup>-bearing nurse cell; BO-97.10 responded only slightly to spleen cells from the same animals. These hybridomas did not react significantly with H-2<sup>d</sup> nurse or spleen cells. A third H-2<sup>b</sup>-derived hybridoma, 2BO-33, did not react with any preparation, and two H-2<sup>d</sup>-derived hybridomas, 22DO-14 and 3DO-54.8, reacted with H-2<sup>d</sup> nurse but not H-2<sup>d</sup> spleen cells. The hybridoma 3DO-54.8 failed to react with the H-2<sup>b</sup> cell

preparations, and 22DO-14 reacted only slightly with both nurse and spleen cell preparations from the H-2<sup>b</sup> mice. Of 35 T-cell hybridomas screened, at least 54% react to some degree with nurse cells from syngeneic mice. By contrast, 26% respond to syngeneic spleen cells, or allogeneic nurse or spleen cells. Usually the reactivities to syngeneic nurse cells are small by comparison with responses to specific antigen plus MHC, or anti-receptor antibody, by the same hybrids. We have been unable to enhance these reactivities by increasing the incubation times of the nurse cells with the T cells, or by adding gamma interferon or indomethacin.

Many of the hybridomas that responded to syngeneic nurse cells were produced by fusion of normal T cells to a derivative of the thymoma, BW 5147 (ref. 17), which does not express functional T-cell receptor  $\alpha$ - and  $\beta$ -chain messenger RNA. The only T-cell receptors expressed on these cells which could be involved in reaction with the syngeneic thymus epithelial cells were therefore those derived from their normal T-cell parents. The hybridoma 3DO-54.8, however, was produced by fusion of a normal T cell to BW5147, which itself contains functional  $\alpha$ - and  $\beta$ -chain mRNA; it may thus express up to four different receptors on its surface, by combination of the normal T-cell and BW receptor polypeptides.

To show that the BALB/c-selected cOVA/I-A<sup>d</sup> receptor on 3DO-54.8 was responsible for the reactivity of this hybrid with syngeneic nurse cells, we tested it and several of its derivatives under various conditions for their ability to respond to BALB/c nurse cells. As before, 3DO-54.8 responded to the nurse cells; this response was inhibited by antibodies to the restricting MHC molecule for 3DO-54.8, I-A<sup>d</sup>. A subclone of the hybridoma, 3DO-54.8.21, in which the  $\beta$ -chain gene inherited from its nor-

mal T-cell parent is absent, did not respond to syngeneic nurse cells, nor did a subclone of 3DO-54.8, 3DO-54.8.43, which no longer expresses CD4. It seems therefore that reaction of 3DO-54.8 with BALB/c nurse cells involves I-A<sup>d</sup> on the nurse cells, CD4 and, probably, the BALB/c T-cell-derived receptor on 3DO-54.8.

Overall, these results indicate that MHC on thymus cortical epithelial cells is not always seen by T cells in the same way as MHC expressed on other cell types. Although nurse cells present antigen plus self-MHC, and in some cases allogeneic MHC, very effectively to some T cells, they are defective in their ability to present alloantigen to other cells: in the present case, I-E to V $\beta$ 17a<sup>+</sup> T cells. As the ligand for V $\beta$ 17a<sup>+</sup> receptors is thought to be a complex of I-E and a B-cell-derived ligand<sup>15</sup>, it is not surprising that thymus cortical epithelial cells, which probably have limited access to B-cell products, do not present it effectively.

More interestingly, MHC on thymus cortical epithelial cells, but not on other cells, can in some cases stimulate hybridomas made from syngeneic T cells, a reaction which may reflect the process of positive selection. These syngeneic responses do not occur with all T cells and are very small, suggesting that the combination of positive selection and tolerance allows only those cells with very weak reactivity for self-MHC to develop into mature T cells, a possibility suggested previously by the work of Ron *et al.*<sup>10,11</sup>. Alternatively, the weak, variable results may reflect the fact that our tests *in vitro* are poor models of the situation *in vivo*, where positive selection probably involves very intimate contact between thymus epithelium and CD4<sup>+</sup>, CD8<sup>+</sup> thymocytes<sup>18</sup>. In either case, the response of T cells to syngeneic thymus epithelial cells, but not to spleen cells, may

FIG. 1 Presentation of antigen, allogeneic MHC and self by thymus cortical epithelial cells.

**METHODS.** Thymuses were removed from 40 6-week-old BALB/c mice, and nurse cells prepared as previously described<sup>12</sup>, using a combination of mechanical disruption, digestion with collagenase (0.1 U ml<sup>-1</sup>, from *Achromobacter iophagus*, Boehringer), dispase (0.8 U ml<sup>-1</sup>, from *Bacillus polymixa*, Boehringer) and bovine pancreas DNase I (0.05 mg ml<sup>-1</sup>), and gravity sedimentation on fetal bovine serum step gradients in the presence of 50 mM EDTA. In the experiment shown,  $2.4 \times 10^5$  nurse cells were obtained, contaminated with an equal number of free thymocytes. Spleen cells were treated with anti-T-cell serum and complement to remove T cells before use as antigen-presenting cells. Nurse or spleen cells were titrated into 250  $\mu$ l microcultures containing  $10^5$  T hybridoma cells and cOVA, where required, at 1 mg ml<sup>-1</sup>. After 24 h, supernatants from these cultures were assayed for interleukin-2 (IL-2) content using HT-2 cells and MTT as an indicator of cell survival<sup>19,20</sup>. This method allows  $<2$  U ml<sup>-1</sup> of IL-2 to be measured accurately. Control cultures, set up with nurse or spleen cells alone,

or with a T-cell hybridoma with no reactivity for BALB/c targets, contained no detectable IL-2. The results shown are those from a single experiment, representative of five similar experiments. Pairs of panels show IL-2 titres with the indicated T-cell hybridomas assayed on nurse or spleen cells. CG4 was produced from a fusion of C57BL/6 anti-BALB/c T cells to BW5147, and is specific for I-E<sup>d</sup>. 3DO-8.2 was produced from a fusion of BALB/c (H-2<sup>d</sup>), cOVA-primed T cells to BW5147. In this experiment 3DO-8.2 showed

no response to BALB/c nurse or spleen cells in the absence of cOVA. 36-19-21 (■), 2Q23-34.7.9 (●) and Q023-26.9 (△) were three V $\beta$ 17a<sup>+</sup> T-cell hybridomas, produced by fusion of SWR T cells to an  $\alpha$ -derivative of BW147 (ref. 17). The 3DO-54.8 was produced from a fusion of cOVA-primed, BALB/c T cells to BW5147. The hybridoma is specific for cOVA/I-A<sup>d</sup>. In this experiment it gave 119 U/ml<sup>-1</sup> IL-2 when challenged with cOVA and BALB/c spleen cells.

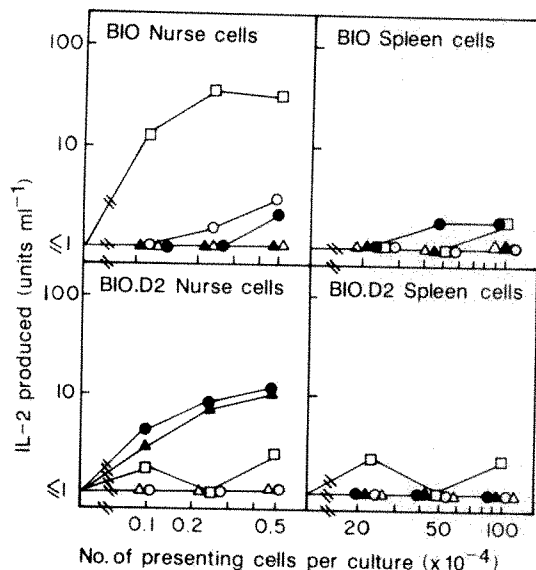

FIG. 2 Some T-cell hybridomas react specifically with syngeneic thymus cortical epithelial cells. Nurse cells were prepared from 19 B10 (H-2<sup>b</sup>) or B10.D2 (H-2<sup>d</sup>) 6-8-week-old mice as described in the legend to Fig. 1. These, and anti-T- and complement-treated spleen cells from the same animals, were tested for their ability to stimulate T-cell hybridomas bearing T-cell receptors from H-2<sup>b</sup> (open symbols) or H-2<sup>d</sup> (closed symbols) mice. Origins of the T-cell hybridomas: BO-97.10 (□) was produced from the fusion of cOVA-primed, C57BL/10 (B10, H-2<sup>b</sup>) T cells to BW5147. 2B0-33 (Δ) and 2B0-43 (○) were also produced from cOVA-primed, B10 cells, but these were fused to an  $\alpha^-$ ,  $\beta^-$ -derivative of BW5147 (ref. 17). 3D0-54.8 (●) was produced as described in the Fig. 1 legend, 22D0-43 (▲) was produced by fusion of cOVA-primed B10.D2 (H-2<sup>d</sup>) T cells to the  $\alpha^-$ ,  $\beta^-$ -derivative of BW5147.

FIG. 3 The normal T-cell-derived receptor and CD4 are required for recognition of restricting I-A on syngeneic thymus cortical epithelial cells by a T-cell hybridoma.

**METHODS.** Nurse cells were prepared from 40 5-week-old BALB/c mice as described in Fig. 1 legend. These, and anti-T- and complement-treated spleen cells, were assayed for their ability to stimulate the BALB/c-derived T-cell hybridoma, 3D0-54.8 (●), and its derivatives, as described in Fig. 1. 3D0-54.8.21 (□) and 3D0-54.8.43 (Δ) were produced by subcloning after prolonged passage of 3D0-54.8 in culture. Southern blots showed that 3D0-54.8.21, which no longer reacts with cOVA/I-A<sup>d</sup>, has lost the only normal T-cell-derived, rearranged  $\beta$ -chain gene characteristic of 3D0-54.8. 3D0-54.8.43, unlike its parent, bears no surface CD4, and reacts very weakly with cOVA/I-A<sup>d</sup>. The anti-I-A<sup>d</sup> monoclonal antibody, MK-D6 was used as a 20% concentration of culture supernatant from the antibody-producing cell line (○).

occur because of quantitative or qualitative differences in MHC expression between thymus epithelial and peripheral cells. We find that thymus cortical epithelial cells do not express a higher density of MHC proteins than cells such as some B-cell lymphomas. Of these two explanations, we therefore prefer the latter; but, of course, the two theories are not mutually exclusive, and both may apply for different T cells. □

## Severe immunodeficiency disease induced by a defective murine leukaemia virus

Douglas C. Aziz<sup>\*†</sup>, Zaher Hanna<sup>\*</sup> & Paul Jolicoeur<sup>\*‡§</sup>

<sup>\*</sup> Laboratory of Molecular Biology, Clinical Research Institute of Montreal, 110 Avenue des Pins ouest, Montréal, Québec H2W 1R7, Canada

<sup>‡</sup> Département de Microbiologie et d'Immunologie, Université de Montréal, Montréal, Québec H3C 3J7, Canada

**DIFFERENT** classes of retroviruses have been shown to induce immunodeficiency diseases in various animal species<sup>1</sup>. These animal models may provide an insight into our understanding of AIDS<sup>1-3</sup> but, with the exception of one strain of feline leukaemia virus<sup>4</sup>, the determinants of pathogenicity have not yet been mapped to these viral genomes. The immunodeficiency-inducing feline leukaemia virus is replication-defective<sup>4</sup>, harbouring the determinant of pathogenicity within its *env* sequences<sup>5</sup>. We have studied the Duplan strain of murine leukaemia virus<sup>6</sup> which induces, in C57BL/6 mice<sup>7-11</sup>, a severe immunodeficiency disease with striking similarities to human AIDS<sup>2,3,8,9</sup>. We have identified the aetiological agent of this murine immunodeficiency disease as another defective retrovirus, with a genome of 4.8 kilobases. Molecular cloning and sequencing of this DNA showed that the *pol* and *env* genes have been deleted, but that the complete *gag* region has been conserved and has a novel sequence encoding the p12 protein. As with the feline leukaemia virus<sup>4,5</sup>, these results provide evidence for the role of defective retroviruses in inducing immunodeficiency and facilitate the study of the mechanisms underlying the pathogenesis of retrovirus-induced immunodeficiency syndromes, including AIDS.

A crude extract containing a mixture of different strains of Duplan murine leukaemia viruses (MuLVs), prepared from a lymph node of a diseased mouse, was used to infect SC-1 cells *in vitro*. Filtered supernatant (SC-1/Dup MuLV) from the

# LETTERS TO NATURE

infected cells induced typical disease within 8 to 12 weeks of inoculation of young adult C57BL/6 mice (Table 1).

To analyse individual viruses present in this crude extract and to identify the retrovirus strain involved in the disease, we first analysed unintegrated viral DNA extracted by the Hirt procedure from SC-1 cells acutely infected with SC-1/Dup MuLV. Using a representative retroviral probe, we detected two

major species of linear viral DNA of 8.8 and 4.8 kilobases (kb), corresponding to a typical full-length non-defective MuLV genome, and to a defective retroviral genome, respectively (Fig. 1a, lane 1). This defective viral genome seemed to be as abundant as the non-defective species in this Hirt supernatant. The viral DNA species in the Hirt supernatant were separated into supercoiled and linear or open-circular viral DNA. The defective

pDu5HNeo DNA was transfected into SIMR cells by the calcium phosphate method<sup>18</sup> and neomycin-resistant colonies were grown in the presence of Geneticin (G418) (200 μg ml<sup>-1</sup>). Twenty-two colonies were picked and rescued with non-pathogenic G<sub>6</sub>T<sub>2</sub> RadLV (ref. 12). To select for the best producer, viruses were collected from the supernatant of each clone, recovered by centrifugation (50 Ti, 35,000 r.p.m. for 30 min) and their RNA extracted by the urea-SDS method<sup>19</sup>. Viral RNA was hybridized with the <sup>32</sup>P-labelled Du5H-specific D30 probe. The best producer was selected to produce stocks. As estimated by hybridization, these stocks contained an approximately three-fold higher concentration of helper viruses than Du5H viruses and the syncytium XC titre<sup>20</sup> of the helper MuLV was 5 × 10<sup>3</sup> plaque-forming units per ml. Young adult (30–40-day-old) C57BL/6 mice were injected intraperitoneally with 0.5 ml twice, one week apart, with medium alone, G<sub>6</sub>T<sub>2</sub> RadLV alone, Du5H rescued with G<sub>6</sub>T<sub>2</sub> RadLV, or with the crude extract of Duplan RadLV. Mice were killed 12–17 weeks after injection when they showed advanced signs of disease (lymphadenopathy). Peripheral lymph-node size varied from 0.4 to 1.5 cm. Spleen cells were suspended into RPMI 1640 medium (Gibco) with 10% fetal calf serum, penicillin G (Sigma) 100 units ml<sup>-1</sup>, streptomycin (Sigma) 100 mg ml<sup>-1</sup> and 10<sup>-5</sup> M β-mercaptoethanol. Aliquots containing 2 × 10<sup>5</sup> cells per 200 μl were distributed in wells of microtest plates (Costar) and incubated at 37 °C for 48 h in humidified atmosphere containing 5% CO<sub>2</sub> with concanavalin A (Con A, Sigma) at 2.5, 5.0 or 10 μg ml<sup>-1</sup>. Cells were incubated for 4 h with 1 μCi of [<sup>3</sup>H]thymidine (42 Ci mmol<sup>-1</sup>) (Amersham) and collected in an automated sample harvester (PHD, Cambridge Technology). Incorporated precursor was counted in a scintillation spectrometer (1215 Rack Beta II, Wallac). The standard error was calculated from an average of 3–5 mice. The concentration of IgM in the sera was measured by a competitive enzyme-linked immunosorbent assay. Polystyrene microtitre plates (Nunc) were coated with affinity-purified mouse IgM (Sigma). Serial dilutions of serum from each mouse were assayed for its ability to inhibit the binding of alkaline phosphatase-conjugated, affinity-purified rabbit anti-mouse IgM (ICN). p-nitrophenyl disodium phosphate (Sigma; 1 mg ml<sup>-1</sup>) was used as a substrate in 1M diethanolamine-HCl (pH 9.8) and 50 mM MgCl<sub>2</sub> and the colour read in the Biotek Model 310 Autoreader at 405 nm. Standard inhibition curves were compared with competitive binding with unconjugated mouse IgM. The standard error was calculated from an average of 3–5 mice.

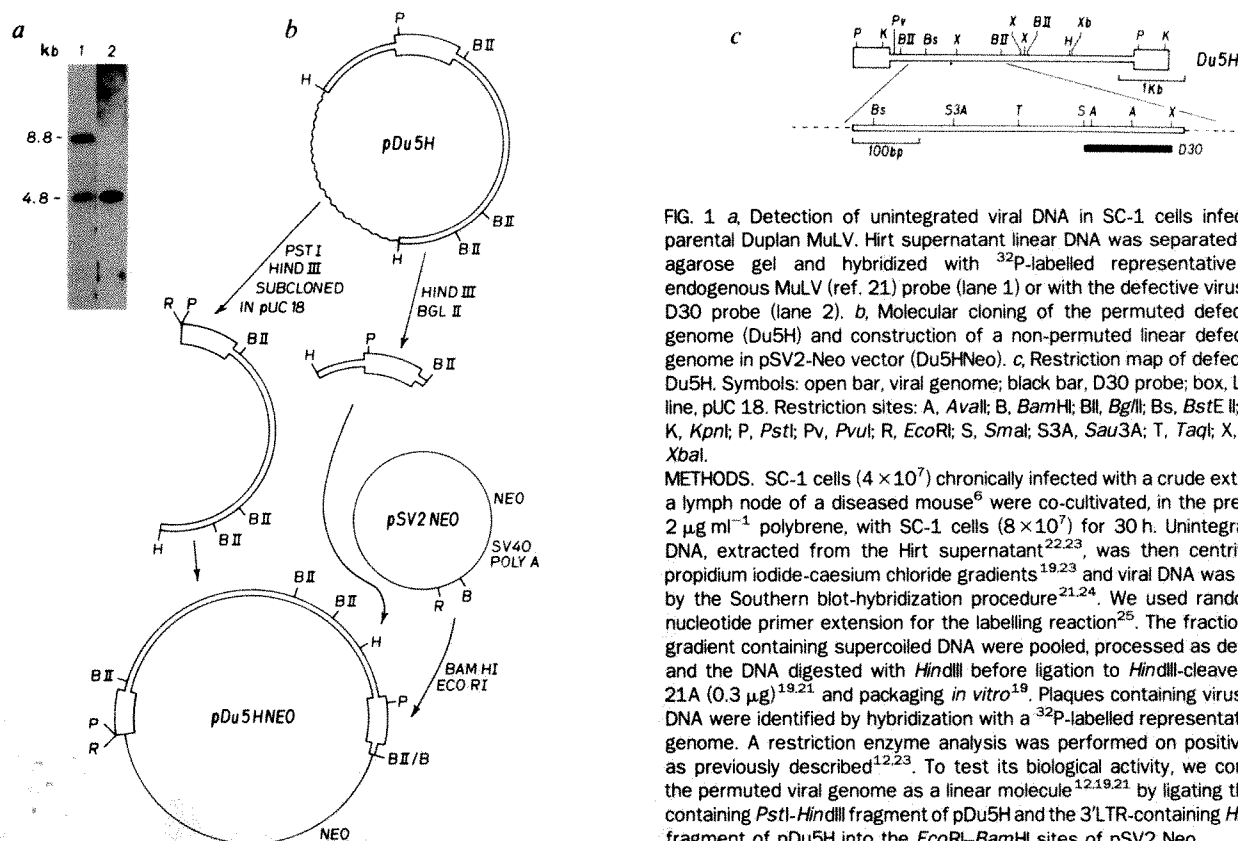

FIG. 1 a, Detection of unintegrated viral DNA in SC-1 cells infected with parental Duplan MuLV. Hirt supernatant linear DNA was separated on 0.7% agarose gel and hybridized with <sup>32</sup>P-labelled representative BALB/c endogenous MuLV (ref. 21) probe (lane 1) or with the defective virus-specific D30 probe (lane 2). b, Molecular cloning of the permuted defective viral genome (Du5H) and construction of a non-permuted linear defective viral genome in pSV2-Neo vector (Du5HNeo). c, Restriction map of defective virus Du5H. Symbols: open bar, viral genome; black bar, D30 probe; box, LTR; wavy line, pUC 18. Restriction sites: A, AclI; B, BamHI; BII, BglII; Bs, BstEII; H, HindIII; K, KpnI; P, PstI; Pv, PvuI; R, EcoRI; S, SmaI; S3A, Sau3A; T, TaqI; X, XhoI; Xb, XbaI.

METHODS. SC-1 cells (4 × 10<sup>7</sup>) chronically infected with a crude extract from a lymph node of a diseased mouse<sup>6</sup> were co-cultivated, in the presence of 2 μg ml<sup>-1</sup> polybrene, with SC-1 cells (8 × 10<sup>7</sup>) for 30 h. Unintegrated viral DNA, extracted from the Hirt supernatant<sup>22,23</sup>, was then centrifuged on propidium iodide-caesium chloride gradients<sup>19,23</sup> and viral DNA was detected by the Southern blot-hybridization procedure<sup>21,24</sup>. We used random hexanucleotide primer extension for the labelling reaction<sup>25</sup>. The fractions of the gradient containing supercoiled DNA were pooled, processed as described<sup>23</sup> and the DNA digested with HindIII before ligation to HindIII-cleaved Charon 21A (0.3 μg)<sup>19,21</sup> and packaging *in vitro*<sup>19</sup>. Plaques containing virus-specific DNA were identified by hybridization with a <sup>32</sup>P-labelled representative MuLV genome. A restriction enzyme analysis was performed on positive clones, as previously described<sup>12,23</sup>. To test its biological activity, we constructed the permuted viral genome as a linear molecule<sup>12,19,21</sup> by ligating the 5'LTR-containing PstI-HindIII fragment of pDu5H and the 3'LTR-containing HindIII-BglII fragment of pDu5H into the EcoRI-BamHI sites of pSV2 Neo.

linear molecules were further purified by agarose gel electroelution and a crude restriction map was obtained (data not shown). *Hind*III cleaved the defective DNA once, but did not cleave the most abundant species of non-defective viral DNA.

To clone the defective viral genome, supercoiled viral DNA was cleaved with *Hind*III and ligated into bacteriophage Charon 21A. Eight clones with an insert of 4.3 kb (one long terminal repeat, LTR) or 4.8 kb (two LTRs) were purified and their inserts subcloned in pUC 18. They all had a similar restriction map which was identical to the map derived from the uncloned Hirt DNA (Fig. 1c). One of these clones (Du5H) was selected and studied further. Several DNA fragments derived from Du5H were subcloned and used as probes to hybridize to the original Hirt DNA. Probe D30, derived from the 137-base pair (bp) *Sma*I-*Xho*I *gag* fragment (Fig. 1c), hybridized to the 4.8-kb species. But it did not hybridize to the 8.8-kb species of the original Hirt DNA (Fig. 1a, lane 2), nor to several other non-defective viral genomes from Moloney, wild mouse neurotropic Cas-Br-E, amphotropic 4070, ecotropic Kaplan V13 radiation leukaemia virus (RadLV) and endogenous ecotropic BALB/c (N-CL-35) MuLVs (data not shown); this suggests that this region of the genome is unique.

To determine whether the presence of the defective viral genome was associated with the disease-inducing potential of this virus, we studied five virus-producing cell lines, cloned from a population of chronically infected SC-1 cells. Three of the lines produced viruses able to induce the same disease as the parental Duplan virus when inoculated into C57BL/6 mice. They also contained a 1.53-kb *Bgl*/II fragment that hybridized to the defective virus-specific D30 probe. The other two lines produced a non-pathogenic virus and did not contain this *Bgl*/II fragment (data not shown). This suggested a role for this defective virus in the disease.

To test the biological activity of the defective viral DNA more directly, it was reconstructed as a non-permuted genome in a selectable vector (Fig. 1b), transfected into SIM.R fibroblasts and rescued with a non-pathogenic helper endogenous RadLV (G<sub>6</sub>T<sub>2</sub>)<sup>12</sup>. Mice injected with this pseudotyped defective MuLV developed clinically apparent disease within 8–12 weeks, as with the crude virus extract (Table 1). Mice inoculated with the helper (G<sub>6</sub>T<sub>2</sub>) alone were free of disease seven months after inoculation. The functional assay for T-lymphocyte response to the mitogen concanavalin A demonstrated that [<sup>3</sup>H]thymidine incorporation was suppressed in spleen cells from mice injected with Du5H

FIG. 2 Nucleotide sequence of defective Duplan Du5H virus. The complete nucleotide sequence is shown together with the predicted amino-acid sequence of the largest open reading frame. The position of sequences encoding Gag p15, p12, p30 and p10 proteins are indicated and the positions of a few restriction endonuclease sites are also shown.

and the resulting fragments were subcloned into pUC18 vector. Plasmid DNAs were prepared by the alkaline method<sup>19</sup>. The sequence was determined by the dideoxynucleotide method of Sanger<sup>26</sup>, using double-stranded supercoiled plasmid DNA as the substrate for the polymerizing enzyme (Sequenase, United States Biochemicals)<sup>27</sup>. Oligonucleotide primers were complementary to the pUC18 vector. Both strands of the viral genome were sequenced.

FIG. 3 Comparison of the restriction map of the defective Du5H viral genome with that of non-defective RadLV (refs 12, 13). Common restriction enzyme sites are indicated. Several large deletions are present in *pol* and *env*. The *gag* sequences are homologous in p15, p30 and p10. Symbols: white box, homologous; black box, deleted; hatched box, unique sequences. BII, *Bgl*II; Bs, *Bst*E II; K, *Kpn*I; P, *Pst*I; Pv, *Pvu*I; PvII, *Pvu*II; X, *Xho*I; Xb, *Xba*I; Circled restriction endonuclease sites are sites present in Du5H, but not in RadLV.

(G<sub>6</sub>T<sub>2</sub>) MuLV, but not in mice injected with helper (G<sub>6</sub>T<sub>2</sub>) alone (Table 1). Serum IgM was also markedly elevated in the Du5H (G<sub>6</sub>T<sub>2</sub>) MuLV-inoculated diseased mice, as compared with the controls (Table 1). Therefore, the defective Du5H genome pseudotyped with a non-pathogenic helper MuLV was sufficient to induce the same disease as the crude Duplan extract, namely lymphadenopathy, splenomegaly, immune suppression and hypergammaglobulinaemia.

To study the structure of this defective viral genome in more detail, we obtained its nucleotide sequence (Fig. 2). Comparison of this sequence with that of other RadLVs (refs 12, 13) revealed several large deletions in *pol* and *env* and a relatively well conserved region in *gag* (Fig. 3). The LTR sequences are very similar to those of the endogenous ecotropic MuLV from C57BL/6 mouse<sup>12</sup>, diverging by only six point mutations in the region U3, one in R and three in the U5 region. They contain only one 99-bp direct repeat in U3. The sequences corresponding to *gag* p12 and to the D30 probe diverged the most from those of other MuLVs. Four large putative open reading frames could be recognized. Three (175, 173 and 170 amino acids; nucleotides 1,175–1,699, 3,241–3,759 and 3,469–3,979, respectively), correspond to part of *gag*, part of *pol* and part of *pol-env*, respectively. The fourth and largest open reading frame (nucleotides 802–2,559) has an ATG codon corresponding to the N-terminus of Gag p15 (nucleotide 970) and continues to p15, p12, p30 and p10. The p15, p30 and p10 showed respectively 81%, 95% and 95% identity to the corresponding amino-acid sequence of AKR MuLV (AKV) (ref. 14), the sequence in the data banks that was closest to it. The Du5H p12 is different from VL3-RadLV (ref. 13) or AKV (ref. 14) p12, however, being shorter by eight amino-acid residues and diverging most notably in its 50-amino acid C-terminus. This unique amino-acid sequence is rich in prolines and has many basic amino-acid residues. A computer search of current entries in sequence libraries revealed that the Du5H Gag p12 C-terminal region had only 40–50% identity with Gag p12 protein of other murine retroviruses, and was not identical to any other non-retroviral sequences in the database.

The pathogenic virus present in the crude Duplan RadLV extract is a unique defective retrovirus capable of inducing a severe immunodeficiency disease after rescue with a non-pathogenic helper ecotropic RadLV. This virus represents the second example, in addition to the variant defective FeLV<sup>4,5</sup>, of an immunodeficiency-inducing retrovirus that is replication-defective. Our results re-emphasize<sup>5</sup> the need to search for similar pathogenic replication-defective variants in other immunodeficiency diseases, including AIDS, and suggest that the pathogenic AIDS virus may also be a defective retrovirus.

The Duplan defective RadLV genome has deleted its *env* region and has a well conserved *gag* region with a unique p12 sequence encoding a putative novel protein. Because this p12-related protein is unique and because of the absence of any other unique long open reading frame, this *gag* region is probably important in the pathogenesis of the disease. Only one

retrovirus, the avian osteopetrosis virus, is known to contain its chief determinant of pathogenicity within its *gag* region<sup>15</sup>. The origin of the unique and shorter p12-related sequence of Duplan defective RadLV remains unclear. It may be derived by recombination between genomic sequences and a primary non-defective RadLV<sup>12</sup>, or it might have evolved by multiple modifications (point mutations, deletions, substitutions and so on of a known *gag* p12 sequence).

The mechanism by which this defective virus induces immunodeficiency remains to be determined, but the similarities of this syndrome with human AIDS are striking. Both viruses induce polyclonal B-cell proliferation, manifested by lymphadenopathy, splenomegaly and hypergammaglobulinaemia, as well as severe immunodeficiency (involving both T-lymphocyte and B-lymphocyte functions), enhanced susceptibility to infections and terminal B-cell lymphomas<sup>2,3,6–11,16</sup>. The presence of T lymphocytes was found to be essential to the development of the murine disease<sup>17</sup>. Therefore, a common perturbation or perturbation of a common pathway may underline this murine syndrome and human AIDS. Further study of this system may lead to better understanding of the pathogenesis of retrovirus-induced immunodeficiency diseases, including AIDS. □

ACKNOWLEDGEMENTS. Sequence data from this manuscript will appear in the EMBL/GenBank/DBJ Nucleotide Databases under accession number X14576 DU 5H. This work was supported by grants to P. J. from the Medical Research Council of Canada and from the National Cancer Institute of Canada. D. C. A. was a recipient of a Fellowship from the National Cancer Institute of Canada. We thank Ginette Massé and Benoit Laganière for technical assistance, Izabella Gorska for help in sequencing DNA, and Drs Jean-François Duplan and Bernard Guillemin for providing the original virus extract.

# Alternative splicing of human dystrophin mRNA generates isoforms at the carboxy terminus

Chris Anne Feener\*, Michel Koenig\*†  
& Louis M. Kunkel\*†

**DYSTROPHIN** is the protein product of the Duchenne/Becker muscular dystrophy locus. It has a relative molecular mass of 427,000 and is encoded by a large RNA transcript processed from more than 65 exons spread over two million base pairs of the human X chromosome<sup>1-5</sup>. We have used the polymerase chain reaction<sup>6</sup> to see whether any of these exons are used alternatively in the different tissues that express dystrophin. As reported for rat dystrophin<sup>7</sup>, we find that the first exon of the human dystrophin transcript is different in brain and muscle, indicating that dystrophin expression could be differentially regulated in these tissues by usage of distinct promoters. The 3' end of the dystrophin transcript can be alternatively spliced to create numerous isoforms differing at their carboxyl domains; this is the only domain of dystrophin that does not share any similarity with the related cytoskeletal  $\alpha$ -actinins<sup>3</sup>. These alternative transcripts yield dystrophin molecules which may interact with different proteins of the tissues expressing dystrophin.

Northern blot analysis of dystrophin messenger RNA from different tissues did not reveal heterogeneity of the transcript in any given tissue, or from one tissue to another (refs 8, 9 and unpublished observations), although minor size variations are difficult to detect. Western blots reveal a predominant protein band corresponding to  $M_r$  427K for dystrophin<sup>1</sup>. Smaller forms are detectable however, and these could represent immunocross-reactive proteins, partial proteolytic breakdown products or isoforms of dystrophin<sup>1,10</sup>. One of these smaller forms ( $M_r$  ~405K) of dystrophin is predominant in smooth muscle of mouse<sup>10</sup>. To test whether alternative splicing is responsible for these differences in protein size, we used the polymerase chain reaction (PCR) (ref. 6) to screen different regions of the human dystrophin mRNA for lost or gained exons. Twelve pairs of primers, derived from the dystrophin complementary DNA sequence<sup>3</sup>, were designed to amplify overlapping segments of ~1 kilobase spanning the entire dystrophin coding sequence. Amplified fragments were visualized directly on polyacrylamide gels or on agarose gels which were Southern blotted and hybridized with cloned skeletal muscle dystrophin cDNA. Any amplified segment of a size not predicted from sequence analysis would indicate a variation resulting from alternative splicing. All segments were amplified from single-stranded cDNA prepared from four different human tissues known to express dystrophin: skeletal muscle (psoas or leg muscles), cardiac muscle, smooth muscle (stomach or aorta) and brain. Tissues expressing lower levels of dystrophin<sup>11</sup> were not analysed.

The sizes of the amplified fragments corresponding to segments 2 to 10 were as predicted from the sequence of dystrophin cDNA from skeletal muscle<sup>3</sup> and were identical for all four tissues tested (Fig. 1b and c). The predicted fragments for the other segments were not uniquely observed in each tissue. The amplified fragment corresponding to segment 1 was found in skeletal, cardiac and smooth muscle, but not in brain tissue (Fig. 1a). This result indicated that the sequence of one of the two primers used to amplify this 5' segment could be absent in the major form of the brain dystrophin transcript. Subsequent blotting of the gel and hybridization with a dystrophin cDNA probe revealed traces of the expected fragment in the brain reaction, possibly as a result of the smooth muscle content of brain (data

not shown). The fragment expected for segment 11 was found in all the tissues we tested, but a smaller and less abundant fragment was also co-amplified (Fig. 1d). The pattern of fragments obtained for segment 12 was more complex. To map this rearranged region more precisely, we amplified segment 12 as two smaller overlapping sub-segments. The amplification of the 5' sub-segment, 12a (Fig. 1e), gave the expected fragment and three other fragments that were smaller by ~40, 100 and 330 base pairs (bp). The amplification of the 3' sub-segment, 12b

**FIG. 1** PCR amplification of six segments of the dystrophin transcript. Amplified products were separated on 1.2% agarose gels (a-c) or on 4% polyacrylamide gels (d-f). Lane 1 is  $\Phi$ X174 replicative form DNA/*Hae*III-cut standard (BRL); lanes 2, 3, 4, 5 and 6 are amplification products of human fetal aorta, brain, heart, leg and stomach tissue respectively. a, Amplification product of segment 1 (position relative to the published cDNA sequence 141-1,207); b, segment 5 (3,770-4,771); c, segment 8 (6,602-7,462); d, segment 11 (9,395-10,342); e, segment 12a (10,288-10,840); f, segment 12b (10,811-11,350). The fragments expected from the skeletal muscle cDNA sequence are indicated by a single white arrow, or a double white arrow when more than one fragment is apparent. The expected fragment of segments 1, 5 and 8 (1,067, 1,002 and 861 bp respectively) is observed in all tissues, except for segment 1 in brain (Fig. 1a, lane 3). In d, a 948-bp fragment is detected along with an unexpected fragment of ~800 bp in length. The lower band appears to be more prevalent in aorta (lane 2) than in other tissues. In e, the expected amplified fragment of 553 bp is seen from all tissues, along with three other fragments of ~510, 450 and 225 bp respectively (material in lane 5 was obtained from a separate experiment). The 553-bp fragment is more prevalent in leg and cardiac muscle, whereas the most prevalent fragment from smooth muscle and brain is 510-bp. The 450- and 225-bp fragments also appear more in smooth muscle and brain than in striated muscles. In segment 12b (f) there are three amplified products (700, 540 and 510 bp). The more prevalent fragment in smooth muscle and brain samples is 510 bp, whereas the expected 540-bp fragment is more prevalent in cardiac and skeletal muscle. We are analysing the 700-bp fragment at present: it could represent use of a new 160-bp exon or simply be an artefact of the PCR, which is supported by the fact that it is not seen under different electrophoresis conditions.

**METHODS.** Total mRNA was isolated by guanidine isothiocyanate extraction<sup>15</sup> and was reverse-transcribed into single-strand cDNA using oligo (dT) (18-25) as primer and reverse transcriptase from Moloney murine leukaemia virus (BRL). Samples were extracted with phenol/chloroform and ethanol-precipitated. The PCRs used 30-mer oligonucleotides (Biopolymers Laboratory, Howard Hughes Medical Institute at Harvard Medical School) which had been purified by electrophoresis on a 20% denaturing polyacrylamide gel. PCR conditions were as recommended (Cetus Corporation), using ~40 ng cDNA and 1  $\mu$ g of each primer. Annealing and primer extension were at 72°C, to minimize artefactual priming, and the denaturation step was at 94°C.

(Fig. 1f), gave three fragments, one of the predicted size, one ~35 bp smaller, and another ~160 bp larger. These results indicate that there are three distinct regions involved in potential alternative splicing in the last 2 kb of the coding sequence. The relative proportions of each fragment within a single sample in segments 11, 12a and 12b differed from tissue to tissue. Analysis of the relative abundance of the fragments indicated that the fragments predicted from the 'skeletal muscle' sequence were indeed more abundant in striated muscles (skeletal and cardiac), whereas the other fragments were usually more abundant in smooth muscle and/or brain.

To investigate the absence of amplification product for segment 1 in brain, we isolated three brain cDNA clones using a 5' skeletal muscle cDNA probe. The sequence of one clone matched the skeletal muscle sequence over the second and third exon, but differed over the entire length of the first exon (Fig. 2a), whereas the sequence of two clones matched the sequence of skeletal muscle cDNA<sup>3</sup> perfectly. The sequence of the alternative first exon indicates that this exon has an in-frame stop codon, followed further downstream by an initiation codon in-frame with the rest of the coding sequence. The alternative first exon would therefore encode only 2½ amino acids (Fig. 2a), replacing the 10½ amino acids of the muscle first exon. To confirm that an alternative first exon is used in brain tissue, we used a primer specific for the alternative exon for the PCR amplification of the corresponding transcript, along with parallel amplification of the 5' end of the skeletal muscle transcript (Fig. 3a and b). We found the alternative first exon in the main form of the brain transcript but also in transcripts of skeletal, cardiac and smooth muscles (Fig. 3b). This same exon has been found in rat brain transcripts<sup>7</sup>. It is striking that the 5' (apparently) untranslated

portion of this exon is highly conserved in human and rat (99% homology; Fig. 2a). In comparison, the 'skeletal muscle' first exon is only 80% homologous between human and mouse<sup>2</sup>. A different first exon in brain implies that there are alternative promoter and regulatory sequences in brain and muscle, which could put expression of dystrophin in these tissues under different control systems.

We investigated the multiple fragments obtained by amplification of segments 11, 12a and 12b by direct sequencing with nested primers. In addition, the sequence of several cDNA clones isolated from skeletal muscle and brain cDNA libraries was determined over the regions involved in differential splicing. In all cases, fragments smaller than those predicted for 'skeletal muscle' resulted from loss of one or more exons, with no replacement of new nucleotide sequences (Fig. 4). The loss of exons in segment 12a maintained the reading frame but the loss of exons in segments 11 and 12b modified the reading frame, resulting in potential coding for new amino-acid sequences. Interestingly, the exon loss in segment 11 results in deletion of the entire carboxyl domain of dystrophin, and the 5' border of the deletion corresponds exactly to the end of the sequence similarity of dystrophin with the carboxyl domain of  $\alpha$ -actinin<sup>3</sup>. Such dystrophin molecules would be formed only by the three domains that are evolutionarily conserved with  $\alpha$ -actinin and might represent an ancestral form of the molecule.

The sequence of skeletal muscle and brain cDNAs confirmed the existence of the most abundant forms of transcript in the two tissues (Fig. 4). However, one skeletal muscle clone has been described as containing a portion of a putative unspliced intron<sup>3</sup> (the position of the splice site was misindicated in Fig. 1 of this ref.) and one of the brain cDNA clones has the same

FIG. 2 5'-Terminal sequence of a brain cDNA clone, including the 'brain' first exon and putative intron sequence found in muscle and brain cDNAs. Exon boundaries are indicated by black triangles and relevant stop codons are underlined. a, Sequence of the first, second and part of third exon of human brain cDNA. The equivalent sequence from rat<sup>7</sup> is shown for comparison. Mismatches are boxed. An ATG codon in frame with the coding sequence is found 7 nucleotides upstream from the first exon border and is preceded by a stop codon in the same reading frame. b, Sequence of the 3' end of two independent cDNA clones containing the same putative intron. The position where the sequence diverges from the skeletal muscle sequence is immediately followed by a typical donor splice site (boxed). The position of divergence is also the 5' border of the coding sequence deletions observed in segment 12a (see text). Numbering is according to the skeletal muscle cDNA sequence<sup>3</sup>. cDNA library construction and screening have been described<sup>2,8</sup>. Both strands of the inserts subcloned into pBR322 or bluescript vectors were sequenced with the Sequenase kit (USB) using universal primers and cDNA-specific oligonucleotide primers.

FIG. 3 Dystrophin transcript amplification using primers from the alternative first exon and from the putative 3' intron. Amplified fragments were separated on polyacrylamide gels. Lane 1 shows  $\phi$ X174 replicative form DNA/*Hae*III-cut standard size markers, as in Fig. 1. Lanes 2, 3, 4, 5 and 6 contain cDNA from human fetal aorta, brain, cardiac, leg muscle and stomach respectively. a and b, Amplification with a 5' primer from the skeletal muscle first exon gives no detectable fragment in the brain reaction (lane 3, panel a), whereas amplification with a 5' primer from the alternative first exon produced the expected 750-bp fragment (white arrow) not only in the brain reaction (lane 3, panel b) but also in the cardiac and leg muscle reactions (lanes 4 and 5, panel b). c, Coamplification of segment 12a with two different 3' primers. One 3' primer is from the dystrophin coding sequence (as in Fig. 1) and the other 3' primer is from the putative intron sequence (positions 10,570 to 10,599 in Fig. 2b). Amplification with the intron 3' primer produced the expected 312-bp fragment (dark arrow) in addition to the four fragments obtained with the coding sequence primers (white arrows; compare with Fig. 1e). RNA preparation, cDNA synthesis and PCR amplification are described in the legend to Fig. 1.

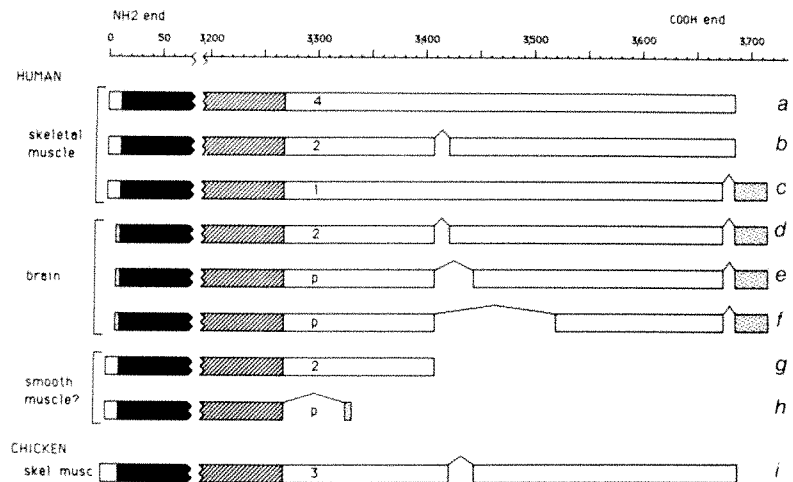

FIG. 4 Summary of possible protein forms encoded by the transcript variants described in this study. N- and C-termini of the dystrophin proteins are represented by bars labelled *a* to *i*. The black and hatched bars represent portions of the domains homologous to the amino and carboxyl domains of dictyostelium  $\alpha$ -actinin respectively. Dotted bars represent amino-acid sequences differing from the published dystrophin sequence. The large open bar represents the carboxyl domain of dystrophin. The numbers indicated in these open bars are the numbers of cDNA clones isolated from brain and skeletal muscle cDNA libraries encoding the corresponding form of the carboxyl domain. *p*, Forms that have been identified solely from the sequence of fragments amplified by PCR. The different forms are not strictly tissue-specific and other forms corresponding to combinations of differentially spliced exons are possible. The tissues in which a particular form is thought to be predominant are shown on the left; 'skeletal' refers to both skeletal and cardiac muscles. The scale is numbered by amino-acid residues and is shown at the top of the diagram. The description of the skeletal muscle form of the chicken dystrophin (*i*) is from Lemaire *et al.*<sup>14</sup>. The different rearrangements at the origin of the forms (*a* to *i*) is as follows; *a*, human skeletal muscle consensus form; *b*, 39-bp deletion (positions 10,432 to 10,470); *c*, 32-bp deletion (11,223 to 11,254); *d*, 'brain' first exon and 39- and 32-bp deletions; *e*, 'brain' first exon, 32-bp deletion and 105-bp deletion (10,432 to 10,536); *f*, 'brain' first exon, 32-bp deletion and 330-bp deletion (10,432 to 10,761); *g*, putative intron sequence (starting at position 10,432, see Fig. 3); *h*, 167-bp deletion (10,016 to 10,182); *i*, 66-bp deletion (positions 10,471 to 10,536 relative to the human cDNA map).

**METHODS.** Cloning and sequencing of the cDNA clones is described in the legend to Fig. 2. Fragments from PCR amplification of segments 11, 12a and 12b were gel-purified before sequence determination. As the different fragments were present in all tissues, they were prepared from the tissue where they were most abundant. The fragments detected in segments 12a and 12b were purified from reactions using brain and heart material and

fragments from segment 11 from aorta. Typically, 5 PCR reactions were pooled and ethanol-precipitated with 0.1% SDS and tRNA as carrier and electrophoresed on 1% low-melting point agarose gels or 4% polyacrylamide gels. Fragments were cut from the gels and either directly purified and concentrated with the GeneClean kit (Bio101) (agarose gels) or electro-eluted in dialysis bags and then purified and concentrated with the GeneClean kit (polyacrylamide gels). After boiling, fragments (100 ng) were directly sequenced with the Sequenase kit ('dGTP' mixes, USB) and S35-dATP (>1,000 Ci mmol<sup>-1</sup>, Amersham). In some cases the concentration of the respective deoxynucleotides in the termination mixes was increased from 8 to 32 mM to maximize the elongation of molecules over the size range of interest (between 100 and 200 nucleotides). The entire sequencing reaction was run on a 6% polyacrylamide gel and exposed for 7 days.

intron sequence (Fig. 2b). Interestingly, the splice site starts at the same position as the deletion variations of segment 12a. Two explanations would account for the finding of two independent clones, apparently representing the same intermediate form of splicing. The splicing machinery could pause at this key intron, resulting in a substantial accumulation of the intermediate form. Alternatively, the intron could be part of a mature transcript. The coding sequence of this transcript terminates at a TGA stop codon contained in the putative donor splice site (see Fig. 2b). The transcript could therefore encode a dystrophin with the last 277 amino acids missing (7.5% of the entire protein), a size corresponding to the smaller form of dystrophin seen on western blots<sup>10</sup>. To confirm the natural occurrence of the putative unspliced intron found in the two cDNA clones, we made a primer from the intron sequence and used it with the previous primers to amplify segment 12a. We detected the predicted 312-bp fragment representing this unusual transcript in all tissues (most prominent in the aorta sample), together with the four fragments seen previously (Fig. 3c). The presence of this 312-bp form in all tissues could be explained either by the smooth muscle content in these tissues, or because it is expressed in all tissues. The fact that we found only two of the cDNA clones out of eleven indicates that this alternative form is probably a minor species in brain and skeletal muscle (the strong intensity of the 312-bp band does not necessarily reflect the relative abundance of this form as the final PCR yield also depends on primer efficiency).

The alternative isoforms of dystrophin we have detected in the amino and carboxyl domains may not represent all possible forms of dystrophin in the cell as the PCR procedure can detect only those forms for which sequence is available. Analysis of cDNA clones from muscle and brain indicates that undetected forms are minor compared with those we present, otherwise they would have been isolated as cDNA clones. The first three domains of dystrophin are similar to those of the cytoskeletal proteins  $\alpha$ -actinin and spectrin<sup>3,12,13</sup> and the terminal 600 amino

acids of dystrophin have been subdivided into two domains on the basis of their cysteine content and similarity to  $\alpha$ -actinin<sup>3</sup>. The variation in the primary sequence (Fig. 4) of dystrophin affects the last domain, which has no counterpart in  $\alpha$ -actinin. It is interesting to speculate on the biological significance of the different forms of this domain in view of the surprising degree of conservation between the human and chicken dystrophin over the last 650 amino acids of the protein<sup>14</sup>, which implies that this terminal domain may interact with other highly conserved structural proteins. Here we have shown that this domain is alternatively spliced, resulting in a potential to encode different polypeptides. Each difference (Fig. 4) is generated by selective removal of exons at three key splice junctions. If the carboxyl domain anchors dystrophin to the inner surface of the plasma membrane through integral membrane proteins, then the discovery of tissue-specific isoforms indicates that proteins which interact with dystrophin could differ between tissues in which dystrophin is expressed. □

# Cotransfection of ICAM-1 and HLA-DR reconstitutes human antigen-presenting cell function in mouse L cells

Daniel M. Altmann, Nancy Hogg\*, John Trowsdale & David Wilkinson†

Human Immunogenetics Laboratory and \*Macrophage Laboratory, Imperial Cancer Research Fund, PO Box 123, 44 Lincoln's Inn Fields, London WC2A 3PX, UK

THE initiation of a specific immune response is believed to require not only activation through antigen-specific receptors on T cells and B cells but also antigen-independent interactions between accessory molecules<sup>1</sup>. One such molecule is LFA-1, which enhances the avidity of interactions between T cells and antigen-presenting cells<sup>2-4</sup>, and is possibly involved in signal transduction across the T-cell membrane<sup>5</sup>. Intercellular adhesion molecule-1 (ICAM-1), a surface glycoprotein of relative molecular mass ( $M_r$ ) 80,000–110,000, has been defined as a ligand for LFA-1<sup>6,7</sup>, and has been shown to participate in the interaction between T cells and monocytes<sup>8</sup>. The determination of the precise contribution of such accessory molecules to antigen presentation, however, is complicated by the need to analyse against a background of multiple molecular interactions. We have investigated the role of LFA-1/ICAM-1 interactions in antigen presentation directly by quantifying the contribution of ICAM-1 expression to T-cell stimulation using L-cell transfectants that co-express ICAM-1 and HLA-DR. In the case of transfectants expressing modest levels of HLA-DR, co-expression of ICAM-1 is critical for effective HLA class II-restricted and allospecific T-cell activation, pointing to an important role for ICAM-1 in the induction of T-cell responses.

Previous studies from our laboratory showed that L-cell transfectants expressing a high level of HLA-DR2 could present antigen efficiently to several antigen-specific, HLA-DR2 restricted T-cell clones without any apparent requirement for LFA-1/ICAM-1 interactions<sup>9</sup>. Some T-cell clones, however, could not be activated in this way, implying that the expression of other human products by the antigen-presenting cells (APC), in addition to HLA class II, was required for effective antigen recognition. Moreover, using L cells transfected with HLA-DR7 (LDR7) (ref. 10), which express levels of HLA class II similar to monocytes, we have been unable to detect any significant antigen or allospecific stimulation of freshly isolated T cells. We therefore investigated whether reconstitution of APC function could be achieved in this case by supertransfecting the HLA-DR7 transfectants with the accessory molecule ICAM-1.

A full-length complementary DNA clone encoding ICAM-1 (ref. 7) was subcloned into the SV40-based cDNA expression vector pJ3 $\omega$  (ref. 11) and used to transfect mouse Ltk<sup>-</sup> cells and L-cell transfectants expressing HLA-DR7 (LDR7) (ref. 10). After flow-microfluorometric sorting and single-cell cloning, cell lines expressing ICAM-1 (L-ICAM-1) and ICAM-1 plus DR7 (LDR7-ICAM-1) were obtained (Fig. 1). Both sets of transfectants bound the ICAM-1-specific monoclonal antibody RR1/1 (ref. 12), their level of expression being similar to that of the B-lymphoblastoid cell line PGF or fibronectin-adherent monocytes. Studies in murine systems have indicated that mouse L cells do not express their own functional ligand for mouse LFA-1 (ref. 13). The level of HLA class II expressed by the LDR7-ICAM-1 transfectants was indistinguishable from that of the parental cell line LDR7, this being  $\sim 1/10$  that observed for the LDR2 transfectants. The large difference in the levels of

HLA class II expressed by LDR7 and LDR2 cells results from the use of different expression vectors during subcloning of the respective cDNA clones used for transfection<sup>9,10</sup>.

Several studies have reported the failure of mouse L cells transfected with HLA products to serve as targets for alloreactive human cells<sup>14,15</sup>. The transfectants L-ICAM-1, LDR7 and

FIG. 1 Flow cytometric analysis of cellular HLA-DR and ICAM-1 expression. Cells were analysed for surface expression of HLA-DR (monoclonal L243) (ref. 17) and ICAM-1 (monoclonal RR1/1) (ref. 12), with rabbit anti-mouse immunoglobulin-FITC as second antibody, by flow cytometric analysis on a FACScan Analyzer (Becton Dickinson). The data are plotted as log fluorescence intensity (in arbitrary units) against cell number. Transfectants were compared with the HLA-DR2Dw2 homozygous B-lymphoblastoid cell line, PGF, and with peripheral blood monocytes prepared by overnight adherence of freshly isolated peripheral blood mononuclear cells to fibronectin-coated dishes. The level of HLA class II expression on monocytes varied among experiments and individuals; the data shown represent a population that falls within the limits of the observed range.

METHODS. Generation and characterization of the LDR7 and LDR2 transfectants has been described in detail elsewhere<sup>9,10</sup>. L-ICAM-1 and LDR7-ICAM-1 transfectants were generated by transfection of Ltk<sup>-</sup> cells and LDR7 cells respectively with an ICAM-1/pJ3 $\omega$  construct using the calcium phosphate precipitation technique. Plasmids encoding neomycin resistance (pSV2neo) or the herpes simplex virus thymidine kinase gene (pOPF) were cotransfected to allow selection of stable transfectants with Geneticin (Gibco) or hypoxanthine/methotrexate/thymidine, respectively. Drug-resistant colonies were pooled and established as stable lines before cloning.

LDR7-ICAM-1 were therefore tested for cytotoxic allorecognition by JLMH1, a DR7-specific alloreactive T-cell line (Fig. 2a). At high effector/target ratios, the LDR7 transfectants showed only marginal specific lysis and no lysis of L-ICAM-1 cells was seen, indicating that neither molecule alone was sufficient to trigger significant effector function. The LDR7-ICAM-1 transfectants, however, served as efficient targets for JLMH1, the contrast with the targets expressing HLA-DR7 alone being most marked at low effector/target ratios. Cytolysis was inhibited by monoclonal antibodies (mAbs) against LFA-1 $\beta$  (the common  $\beta$ -chain of the LFA-1 family<sup>16</sup>, ICAM-1 (ref. 12), HLA-DR (ref. 17) and CD4 (Leu3a) (Fig. 2b). Thus, the inefficient allorecognition

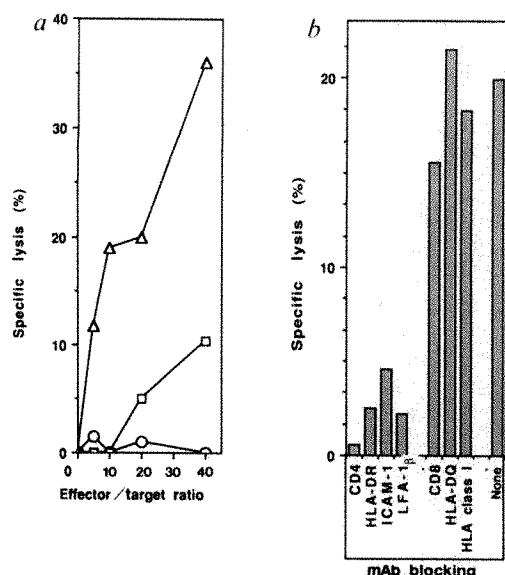

FIG. 2 Role of ICAM-1 in lysis of transfectants by cytotoxic T-cells. *a*, Target cells ( $1 \times 10^4$  per well) were labelled with  $^{51}\text{Cr}$  (Amersham) and cultured at the indicated effector to target ratios with JLMH1 T-cells in V-bottom wells for 7 h, at which time supernatants were counted in a Beckmann Gamma 4000 Counter. Each point represents the mean of triplicate cultures. JLMH1 is a long-term,  $\text{CD4}^+$ , alloreactive T-cell line, initially generated by stimulation of PBM cells from an HLA-DR4Dw4 homozygous individual with cells from an HLA-DR7 homozygous individual. The line is HLA-DR7-specific, recognizing all HLA-DR7 positive B lymphoblastoid cell lines but not HLA-DR1 or DR6 cell lines. Lysis of the HLA-DR7 homozygous B-LCL MANN was 83% (E/T=40). Circles, L-ICAM-1; squares, LDR7; triangles, LDR7-ICAM-1. *b*, Cytolysis of the LDR7-ICAM-1 transfectant was assessed at an effector/target ratio of 20 in the presence of various mAbs. Antibodies were added to cultures as a 200-fold dilution of purified immunoglobulin or ascites representing a final concentration of  $10\text{--}15 \mu\text{g ml}^{-1}$ . Monoclonals used: Leu3a (anti-CD4); L243 (anti-DR1 $^7$ ); RR1/1 (anti-ICAM-1)<sup>12</sup>; MHM23 (anti-LFA-1 $\beta$  chain)<sup>16</sup>; OKT8 (anti-CD8); Genox 3.53 (anti-HLA-DQw1); and W6/32 (anti-HLA class I).

of LDR7 was not due to the qualitative absence of a cell-type specific alloantigenic peptide, as has been suggested following the failure to observe allorecognition in other transfection systems<sup>15,18</sup>, but rather reflects a quantitative dependence of T-cell recognition and/or effector function on accessory molecule interactions. Moreover, if allorecognition depends on low-affinity, cross-reactive recognition by T-cell receptors<sup>19</sup>, then accessory molecule interactions could make an important contribution to overall intercellular avidity.

A more stringent test of APC function is the presentation of antigen or alloantigen to freshly isolated peripheral blood mononuclear (PBM) cells. When the LDR7 transfectants were tested for the ability to stimulate alloreactive responses in HLA-mismatched PBM, they elicited no response (Fig. 3). In marked contrast, the LDR7-ICAM-1 transfectants stimulated large responses from non-HLA-DR7 (but not HLA-DR7) individuals, suggesting an important role for ICAM-1 in the induction of an alloreactive response against HLA-DR7 on these cells. But under identical conditions, the LDR2 transfectants, which express extremely high levels of HLA class II (Fig. 1), stimulated strong proliferative responses from non-HLA-DR2 PBM, without any requirement for ICAM-1 co-expression. These results provide evidence for a synergistic relationship between HLA class II and ICAM-1 in T-cell stimulation, the expression of ICAM-1 being of crucial importance under conditions of

FIG. 3 Stimulation of freshly isolated peripheral blood mononuclear cells by allogeneic transfectants. Transfectants ( $5 \times 10^4$  per flat-bottom well) were treated with  $100 \mu\text{g ml}^{-1}$  mitomycin c (Sigma) at  $37^\circ$  for 1 h before co-culturing in Iscoves' modified Dulbecco's medium (Gibco Laboratories) with  $1 \times 10^5$  freshly isolated peripheral blood mononuclear cells from individuals of the indicated HLA-DR types. Responses of donors to complete HLA haplotype-mismatched B-LCL ranged  $105,000\text{--}182,000$  c.p.m. Cells were cultured for 6 d, adding  $1 \mu\text{Ci ml}^{-1}$  [ $^3\text{H}$ ] thymidine (Amersham) for the final 6 h before collecting onto filter sheets and counting in a 1205 Betaplate scintillation counter (LKB). Bars represent the mean responses ( $\pm$  s.e.) from triplicate cultures.

FIG. 4 Presentation of purified protein derivative (PPD) to freshly isolated T-cells by LDR7-ICAM-1 transfectants. *a*, Freshly isolated peripheral blood mononuclear cells from an HLA-DR2,7 individual ( $1 \times 10^5$  per well, irradiated with 40 Gy), LDR7 transfectants or LDR7-ICAM-1 transfectants (treated as described in Fig. 3 legend) were tested for the ability to present PPD of *M. tuberculosis* (Statens Serum Institute, Denmark) added at a concentration of  $25 \mu\text{g ml}^{-1}$  to autologous, nylon-wool-purified T-cells ( $1 \times 10^5$  per well). T-cells cultured with PPD in the absence of added APC gave a response of  $1,168 \pm 485$  c.p.m. Other details of culture and collecting are given in the legend to Fig. 3. Antibodies (details as in Fig. 2) were added to cultures containing purified T-cells, LDR7-ICAM-1 transfectants and PPD as in the lower part of panel *a*.

limiting HLA class II expression by the allogeneic stimulator. Similar synergistic effects between LFA-1 and class II have been reported in murine T-cell responses to antigen<sup>2</sup>. Given that the absolute level of HLA class II expressed by the LDR7 transfectants is similar to that of activated monocytes, this dramatic effect of ICAM-1 on T-cell stimulation is probably of physiological relevance.

Alloreactive T-cells may differ in their activation requirements from antigen-specific, HLA-restricted T-cells. We therefore investigated the importance of ICAM-1 expression by the APC in recall antigen responses of freshly isolated T-cells. When purified T-cells from an HLA-DR7 responder were tested for their ability to respond to a purified protein derivative of *Mycobacterium tuberculosis* (PPD), a marginal response was observed using LDR7 cells as APC (Fig. 4a), which was amplified by co-expression of ICAM-1. Antigen presentation by the LDR7-ICAM-1 transfectants was inhibited by antibodies to HLA-DR, LFA-1 $\beta$ , and ICAM-1 (Fig. 4b), confirming the HLA class II restriction and LFA-1/ICAM-1 dependence of the response. The LDR7-ICAM-1 transfectants also induced some T-cell proliferation in the absence of exogenous antigen or allogeneic HLA-DR (Fig. 4a). Indeed, L cells transfected with ICAM-1 alone delivered a small but significant mitogenic signal to purified T-cells which, although not as pronounced as the allorecognition demonstrable with LDR7-ICAM-1 transfectants, was significant compared with the response against control Ltk<sup>-</sup> cells and was specifically inhibited by mAbs against ICAM-1 or LFA-1 $\alpha$  (data not shown). Although enhancement of a small xenogeneic response to mouse class I antigens cannot be discounted, these results suggest that the effects on recognition that follow transfection of ICAM-1 may involve not only enhanced conjugate formation with T-cells, but the delivery of activation signals through the ICAM-1/LFA-1 interaction itself. Such a pathway is implied by the T-cell mitogenic effect of some LFA-1 antibodies<sup>5</sup>.

Using DNA-mediated gene transfer we have been able to define the contribution of LFA-1/ICAM-1 interactions to antigen presentation in a manner not complicated by the expression of other APC-derived accessory molecules. In the absence of high levels of HLA class II expression by the APC, ICAM-1 expression can be a decisive factor in determining whether a T-cell response occurs. This observation is relevant not only to haemopoietic APC but also to cells of non-haemopoietic origin such as fibroblasts<sup>20,21</sup>, endothelial cells, and epidermal keratinocytes<sup>22,23</sup>, which express both HLA class II and ICAM-1 following exposure to interferon- $\gamma$ , and may therefore serve as APC for self and foreign antigens<sup>24</sup>. In addition, the profound effects of ICAM-1 expression on T-cell stimulation may have direct bearing on the relationship between the lack of expression of ICAM-1 (as well as other accessory molecules) on Epstein-Barr virus Burkitt's lymphoma lines and their inability to be recognized by anti-Epstein-Barr virus cytotoxic T-cells<sup>25</sup>. □

## Compliance of bacterial flagella measured with optical tweezers

Steven M. Block\*†, David F. Blair†  
& Howard C. Berg\*†

\* Rowland Institute for Science, 100 Cambridge Parkway, Cambridge, Massachusetts 02142, USA

† Department of Cellular and Developmental Biology, Harvard University, 16 Divinity Avenue, Cambridge, Massachusetts 02138, USA

THE development of the gradient force optical particle trap ('optical tweezers') has made it possible to manipulate biological materials using a single beam of laser light<sup>1</sup>. Optical traps can produce forces in the microdyne range on intact cells without causing overt damage: such forces are sufficient to arrest actively swimming bacteria<sup>2</sup> and can overcome torque generated by the flagellar motor of a bacterium tethered to a glass surface by a flagellar filament. By calibrating the trapping force against Stokes' drag and measuring the twist that is sustained by this force, we determined the torsional compliance of flagella in tethered *Escherichia coli* and a motile *Streptococcus*. Flagella behaved as linear torsion springs for roughly half a revolution, but became much more rigid when turned beyond this point in either direction.

Many motile bacteria are propelled by flagellar filaments, each of which is turned at its base by a reversible rotary motor driven by a transmembrane proton gradient<sup>3-5</sup>. In *E. coli*, the filament is a long helical polymer of a protein, flagellin, of molecular weight about 55,000. The filament is joined to the motor by means of a short hook (~80 nm long), a polymer of another protein, that is believed to serve as a flexible coupling<sup>3,5</sup>. The filament, hook and motor (or basal structure) constitute the flagellum. Wild-type filaments are polymorphic: left- and right-handed forms have been described with a variety of helical pitches, depending on pH, ionic strength and torsional load<sup>5</sup>. Under normal physiological conditions, they assume a left-handed configuration, with wavelength ~2.5  $\mu$ m. When the motors turn anticlockwise (as viewed looking down the filament at the cell), the filaments move together to push the cell forward. When the motors turn clockwise, the filament bundle flies apart and the cell tumbles. Polymorphic transitions have been observed during tumbling which convert the filaments to right-handed forms with roughly half the wavelength<sup>6</sup>. When tethered to a surface by a single filament, a cell spins alternately clockwise and anticlockwise at nearly the same angular speed, changing direction abruptly and at random<sup>7,8</sup>, some cells occasionally pause<sup>9</sup>. At room temperature, filaments in bundles spin at about 100 Hz, whereas tethered cell bodies spin at about 10 Hz. The motor exerts its maximum torque at stall, dropping monotonically with increased speed<sup>10</sup>.

Here we used cells whose motors had been paralysed by mutation, or de-energized by starvation or treatment with agents that dissipate the transmembrane proton gradient. These cells were tethered and spun by an external torque that was applied with an optical trap (Fig. 1). The central component is an infrared laser (wavelength 1,064 nm) whose beam is brought to a diffraction-limited focus by an objective of high numerical aperture. Transparent refractile materials such as bacteria experience forces that arise from induced dipole interactions

with the light gradient, which tend to pull them into a trapping zone located just beyond the focus. The dimensions of the zone are comparable with the wavelength. Beam-steering optics allow the trap to be positioned manually in  $x$ ,  $y$ , and  $z$  dimensions and swept electronically clockwise or anticlockwise in a circle in the  $x$ - $y$  (specimen) plane. The laser is equipped with an attenuator to adjust the force and with a shutter to gate the trap.

At a low Reynold's number ( $\sim 10^{-5}$  in the case of *E. coli*), the externally applied torque is balanced by torques arising from viscous drag on the cell body, torsion in the tether and thermal motion

$$f_{\theta}\Omega(t) + k_{\theta}\theta(t) + L(t) + N(t) = 0 \quad (1)$$

where  $f_{\theta}$  is the rotational drag coefficient of the cell body,  $\Omega(t)$  is its angular velocity,  $k_{\theta}$  is the torsional spring constant of the tether,  $\theta(t)$  is its twist,  $L(t)$  is the Langevin torque arising from random bombardment by molecules in the medium,  $N(t)$  is the applied torque and  $t$  is the time. Three kinds of behaviour can be distinguished, depending on the degree to which the motor resists rotation. (1) The motor turns freely, that is, it swivels about its tether and  $k_{\theta}\theta$  vanishes. (2) The motor locks up partially, that is, it fails to turn until the torque arising from twist in the tether reaches a finite value, whereupon it slips;  $k_{\theta}\theta$  has some upper bound. (3) The motor locks up entirely, that is, the cell body becomes clamped to the end of the tether, in which case  $\Omega(t) = d\theta/dt$ . Measurements on partially or fully locked cells enable  $k_{\theta}$  to be determined. Note that for small angular deviations, the behaviour of partially or fully locked cells is the same.

*E. coli* carrying mutations in *motA* or *motB*, the genes implicated in torque production, have flagella that fail to rotate<sup>11-13</sup>. We found that tethered cells in which either or both genes had been deleted diffused freely, as judged by videotape recordings and time-exposure photomicrographs; the time for a random excursion through  $2\pi$  radians was typically several minutes, consistent with free Brownian rotation. When these cells were

spun through several revolutions by the optical trap and then abruptly released by shuttering the laser, they stopped in place. The external torque required to rotate cells carrying the double deletion  $\Delta(motA-motB)$  was proportional to the angular velocity (measured from  $0.4 \times 10^{-11}$  dyne-cm at 0.5 Hz to  $2.6 \times 10^{-11}$  dyne-cm at 3.0 Hz); least-squares fits passed through the origin.

Measurements of this kind were quantitated by calibrating the trap against Stokes' drag. A free cell was captured by the trap; this orientated its long axis parallel to the beam. The light level was fixed with the attenuator and the cell was moved along a circular trajectory ( $\sim 4 \mu\text{m}$  in diameter). This path was retraced at increasing angular velocity until the transverse drag on the cell was just sufficient to pull it from the trap, that is, until the trapping force was balanced by Stokes' drag. This 'critical angular velocity' was recorded over the range of attenuator settings and a calibration curve constructed. As anticipated, this velocity (and hence the force) was strictly proportional to light level. The drag force was computed from the critical angular velocity, circumference of the trajectory, viscosity, and the transverse linear drag coefficient for that cell. To compute the drag coefficient, the cell's shape was approximated by a cylinder with hemispherical endcaps<sup>14</sup>; measurements of its dimensions were made from recordings using a computer-based video measurement system under conditions of negligible blooming<sup>15</sup>. Torques applied to tethered cells were computed from the product of the trapping force and the trap eccentricity (distance from centre of trap to centre of rotation). A correction factor equal to the aspect ratio of the cell was applied to the calibration to compensate for the optical path through the cell being shorter when its long axis was perpendicular to the laser beam. This correction gave excellent agreement between the measured slopes of the torque-velocity curves for  $\Delta(motA-motB)$  cells and their computed rotational drag coefficients<sup>14</sup>.

Wild-type cells normally spin when tethered, but their motors

FIG. 1 Sketch of a bacterial cell being rotated about its tether by the optical trap. The axis of rotation of the trap (dashed line) was aligned with the tether (short thick line). The sense of rotation is shown by the circular arrow. Two views of the cell are displayed, at  $\theta = 0^\circ$  (solid lines) and  $\theta = 180^\circ$  (dotted lines). The laser beam enters from above, through the coverslip, as shown by the crossed rays. The microscope illumination (not shown) enters from below.

**METHODS.** Cells of *E. coli* strains RP437 (wild type for motility and chemotaxis), RP6665 ( $\Delta(motA-motB)$ ), RP421 (*motB*<sup>580</sup>) and RP6894 ( $\Delta(motA-motB)$ ) containing plasmid SYC62 encoding wild-type *motB* (gifts from S. Parkinson) were grown at 35 °C in tryptone broth, washed twice in buffer, shorn, washed twice again, and tethered as described<sup>24</sup>, except that the buffer was 0.01 M potassium phosphate, pH 7.0, made 0.067 M in NaCl and  $10^{-4}$  M in EDTA, and cover slips were cleaned with acetone followed by saturated KOH in ethanol. Cells of *Streptococcus* strain V4051 were grown at 35 °C in 1%  $\text{K}_2\text{HPO}_4$ , 1% tryptone, 0.5% yeast extract, 1% glucose medium, washed twice in buffer, shorn, washed twice again, and tethered as described previously<sup>25</sup>, except that the buffer used was 0.01 M TES, 0.01 M MES (pH 8.5), 0.2 M KCl,  $10^{-4}$  M EDTA; cover slips were cleaned as above. The cover slips were mounted in a small flow cell<sup>26</sup>. Experiments were at room temperature. *E. coli* were de-energized by flowing in buffer containing 2,4-dinitrophenol (DNP, 3 or 10 mM) for several minutes. *Streptococci* were de-energized by starvation for  $\geq 30$  min in buffer, or by treatment with buffer containing DNP (3 mM) or trifluoromethoxycarbonyl-cyanide phenylhydrazine (FCCP,  $10 \mu\text{g ml}^{-1}$ ). To suppress possible photodynamic effects with DNP, a 1 cm-thick filter containing DNP ( $\sim 10$  mM) was interposed between the microscope lamp and the specimen. The optical trap comprised a Nd:YAG diode-pumped microlaser (Amoco Laser Co., ALC-1064, selected for 95 mW power output), a  $3\times$  beam expander, a relay lens (CVI Laser, laser aplanat) held by a micropositioner, an infrared/visible dichroic mirror (CVI Laser) mounted in the epi-head of a research microscope (Zeiss, Universal), and a phase-contrast objective of high numerical aperture (Nikon, 60 $\times$  Planapo, DM series, 1.4 NA). The beam diameter was adjusted to fill the rear pupil of the objective. Light intensity was varied with a dual-wedge compensating attenuator (Newport, 925B) and gated by an electronic shutter (Uniblitz, 26L). Coarse  $x$ - $y$  beam steering and  $z$ -focusing were achieved by adjusting the position of the relay lens with micrometer

screws. The relay lens was mounted at the end of a rigid cantilever; fine  $x$ - $y$  steering was achieved by energizing coils that wrapped around this cantilever and extended through fields generated by permanent magnets. The steering system had a resonant frequency of 33 Hz and was critically damped with a dashpot filled with a halocarbon oil. The coils were driven by a quadrature oscillator that produced circular displacement of the lens: the direction, centre position, speed and amplitude of the circle were adjustable. The trap position was monitored by a charge-coupled device camera (Pulnix, TM-840N) that picked up the infrared reflection of the beam spot off the cover slip; the same camera was used to videotape all experiments. In control experiments designed to assess possible damage caused by high laser light levels, *Streptococcus* was tethered in growth medium and arrested with the beam at full power. The beam was gated off for a few seconds every minute to release the cell and allow it to spin. No reduction in motility was observed over a period of hours; indeed, the cell elongated and eventually divided. *E. coli* was far less resistant to light; cells lost motility after several minutes' exposure. Therefore, we used minimal light levels and kept the laser shuttered at all times when measurements were not being made.

can be arrested by treatment with protonophores such as 2,4-dinitrophenol (DNP) and trifluoromethoxycarbonyl-cyanide phenylhydrazone (FCCP). In the case of *Streptococcus*, motors can also be halted by starvation<sup>4</sup>. These treatments produced a range of phenotypes. In contrast with previous reports<sup>4,16</sup>, we found that many of these cells were able to diffuse freely. In some cases this motion was hindered at certain fixed angles, probably as a result of interactions with the tethering surface. Other cells locked up, either partially, so that the cell could still be driven through many revolutions with the light trap, or entirely, so that it could not. When a partially locked cell was spun through several revolutions and then abruptly released, the cell body rebounded elastically through a fraction of a revolution (typically 60°). For example, in an experiment with starved *Streptococcus*, a cell was spun either clockwise or anticlockwise at 1.5 Hz for several seconds and then released at a random angle. The rebound angle was distributed normally with a mean and s.d. of  $61^\circ \pm 27^\circ$  ( $n=108$ ). The amplitude of the recoil seemed to be independent of the direction of rotation and diminished by only 15% when the initial angular velocity was halved. There was no obvious spatial periodicity to the angular positions of the cell after rebounding. When we measured the external torques that were required to turn partially locked, DNP-treated cells of *E. coli* as a function of angular velocity, we obtained straight lines which were displaced upwards from the origin by  $\sim 2 \times 10^{-12}$  dyne-cm. This corresponds to an additional torque required to overcome the barrier caused by the partial lock-up.

The lock-up behaviour of protonophore-treated *E. coli*, or of starved or protonophore-treated *Streptococcus*, implies the presence of an energy barrier to rotation which is larger than  $kT$ , where  $k$  is Boltzmann's constant and  $T$  is the absolute temperature. A typical record of jitter angle for *Streptococcus* is displayed in the inset to Fig. 2. By the equipartition theorem,  $kT/2 = k_\theta \langle \theta^2 \rangle / 2$ , permitting an estimate of  $k_\theta$  directly from the mean-square angle<sup>16</sup>. For this cell, we obtained  $k_\theta = 1.18 \times 10^{-12}$  dyne-cm rad<sup>-1</sup>. The autocorrelation of the angle,  $I(\tau)$ , is obtained by solving equation (1) with  $N(t)=0$  and  $\Omega(t) = d\theta/dt$ , giving  $I(\tau) = I_0 \exp(-|\alpha\tau|)$ , where  $\tau$  is the lag

FIG. 2 Noise analysis of tethered *Streptococcus*. The graph shows the normalized autocorrelation function (squares) of angular jitter due to Brownian rotation of a partially locked *Streptococcus* cell treated with FCCP. The data were fitted by an exponential of time constant 0.875 s, solid line. Inset: The data from which the autocorrelation was computed, showing the angular position of this cell for 26.4 s. The root-mean square amplitude of the angular distribution was  $10.7^\circ$ .

**METHODS.** The autocorrelation as computed by standard fast-Fourier-transform technique<sup>27</sup> from an 800-point record of the angular position, with points digitized at every video-frame interval (1/30 s). Angles were measured with a computerized 'video protractor' coupled to an incremental shaft encoder (Vernitec, VEOL-23). Measurement error, determined from recordings of stuck cells, was  $\pm 4^\circ$ . Mean-square angle is a biased estimator, because zero-mean noise adds as a square, so values were corrected by subtracting the squared measurement error.

time and  $\alpha = k_\theta / f_\theta$  (ref. 17). The experimental data are fitted by an exponential of time constant  $\alpha^{-1} = 0.875$  s (Fig. 2). The rotational drag coefficient,  $f_\theta$ , was estimated from the cell's geometry and the viscosity<sup>13</sup>, giving  $k_\theta = \alpha f_\theta = \alpha f_\theta = 1.21 \times 10^{-12}$  dyne-cm rad<sup>-1</sup>.

A more direct measurement of  $k_\theta$  was made from the kinetics of the rebound that occurred when a partially locked cell was spun and released (Fig. 3). In this relaxation experiment,  $N(t)$  is reduced from a fixed value to zero, and  $\theta(t)$  decays as  $\exp(-\alpha t)$  to zero. The upper curves display the angle as a function of time after release, using the same cell as shown in Fig. 2. The angle relaxed exponentially, as required by equation (1), with time constant  $\alpha^{-1} = 0.745$ , giving  $k_\theta = \alpha f_\theta = 1.42 \times 10^{-12}$  dyne-cm rad<sup>-1</sup>. This value is slightly larger than that obtained by noise analysis, in which a small amount of drift in the steady-state angular position would exaggerate  $\langle \theta^2 \rangle$ , leading to an underestimate of  $k_\theta$ . The lower curves of Fig. 3 show analogous data for *E. coli*, with a time constant of  $\alpha^{-1} = 0.143$  s, nearly five times faster, and giving  $k_\theta = 4.03 \times 10^{-12}$  dyne-cm rad<sup>-1</sup>. Cells of *E. coli* are smaller and their flagella appear to be more than twice as stiff, a property reflected in the small root-mean-square jitter observed in tethered *E. coli* ( $\sim 6^\circ$ ), compared with *Streptococcus* ( $\sim 11^\circ$ ).

A motor driving a tethered cell of *Streptococcus* generates a torque of  $\sim 3 \times 10^{-11}$  dyne-cm<sup>10</sup>. Were the flagellum to behave as an ideal spring throughout its full range of movement with  $k_\theta \approx 1.3 \times 10^{-12}$  dyne-cm rad<sup>-1</sup> (the value determined above), it would twist nearly four complete turns when subjected to this torque. Were the motor to reverse suddenly, the cell body would not follow suit until the flagellum had unwound four turns, and it would not reach top speed until the flagellum had wound up four turns in the opposite direction. Even if the motor were run at its maximum speed throughout this manoeuvre (100 Hz at room temperature<sup>10</sup>), the reversal would take roughly 0.1 s. Reversals are much more abrupt than this ( $< 0.01$  s for *E. coli*<sup>16</sup> and  $< 0.03$  s for *Streptococcus*; S.M.B., D.F.B. and H.C.B., unpublished data).

FIG. 3 Relaxation experiments with partially locked bacteria. The upper curve in the main plot shows the angle of the *Streptococcus* cell of Fig. 2 as a function of time, digitized at each video-frame interval. The cell was driven anticlockwise by the light trap and released at the time indicated by the arrow. The cell rebounded clockwise, relaxing to equilibrium. The lower curve shows a similar experiment with a wild-type cell of *E. coli* treated with 10 mM DNP. Inset: Semilog plots of these data from the time of the arrows, after subtraction of the baseline angle, and linefits (solid lines) showing the exponential character of the relaxation. Time constants for decay and computed rotational drag coefficients: 0.745 s,  $1.06 \times 10^{-12}$  dyne-cm rad<sup>-1</sup> s<sup>-1</sup> and 0.143 s,  $5.76 \times 10^{-13}$  dyne-cm rad<sup>-1</sup> s<sup>-1</sup> for *Streptococcus* and *E. coli* respectively.

**METHODS.** The attenuator was set to produce negligible trapping force, the angular speed was set to 0.5 Hz, and the trap was aligned with a tethered cell, as illustrated in Fig. 1. The beam was then shuttered and the attenuator reduced to a setting that gave strong trapping. The shutter was opened and the cell spun at a fixed speed between 0.5 and 2 Hz for a few seconds, at which point the shutter was closed and the angular relaxation recorded.

We resolved this paradox by determining compliance over a large angular range. Figure 4 shows the torsion angle as a function of torque for cells whose motors appeared fully locked. In this domain, for sufficiently slow rotation,  $N \approx -k_\theta \theta$ . The compliance (slope) shows linear elastic behaviour through some  $100^\circ$  of twist (with a value of  $k_\theta$  similar to that found above), and then it becomes more than an order of magnitude stiffer. Because of the nonlinearity, a tethered cell needs only to twist its flagellum about half a turn before it becomes rigid; therefore, a reversal could be completed within one turn, namely in  $\leq 0.01$  s. In a parallel experiment, a wild-type cell was arrested by gentle fixation with glutaraldehyde. The compliance was symmetric for both clockwise and anticlockwise rotations (Fig. 4, inset). The smaller asymptotic angle observed for this cell might reflect the difference in tether lengths, which can vary from cell to cell.

FIG. 4 Compliance curves for locked bacteria. The graph shows the angular displacement of fully locked cells as a function of the torque applied by the optical tweezers. Dashed line, data from a cell of *Streptococcus* treated with 10 mM DNP. Value for  $k_\theta$  at small angles  $\sim 2 \times 10^{-12}$  dyne-cm rad $^{-1}$ . Solid line, data from a cell of *E. coli* treated with 10 mM DNP. Value for  $k_\theta$  at small angles  $\sim 5 \times 10^{-12}$  dyne-cm rad $^{-1}$ . Error bars show the standard deviation for ten or more determinations of angle. Inset: Compliance curve for a cell of *E. coli* fixed with 0.1% glutaraldehyde in buffer, showing symmetry for clockwise and anticlockwise rotation.

**METHODS.** Cells which were apparently locked at a fixed angle were found by trial and error after treatment with 10 mM DNP. The trap was aligned as illustrated in Fig. 1, its speed was fixed at 0.25 Hz, and the eccentricity adjusted to maximize the torque. Then the beam was shuttered. The attenuator was reduced in a series of steps and the shutter opened for a short time at each level. As the trap encountered the cell body, it entrained it, turning it through part of a revolution until the trapping torque just balanced the elastic reaction of the tether. At this point, the cell escaped from the trap and rebounded to its original angle. This process was repeated at least ten times for each setting of the attenuator. Single-frame analysis with the video protractor provided the maximum angle attained for each trial. The force calibration curve and the trap eccentricity were used to convert the attenuator settings to torque. For most cells of *Streptococcus* (tethered without antibody), the highest values of torque would twist the cell off the tethering surface, terminating the experiment; this did not occur for cells of *E. coli* (tethered with antibody). In one instance involving *Streptococcus*, the cell remained well tethered, but the cell body suddenly stopped rebounding, remaining instead where it was when the beam was shuttered. Either the mechanism responsible for the lock-up was overcome or a component of the motor was broken. The torsion constant of a uniform hollow tube is related to the torsional rigidity,  $\mu$ , by  $k_\theta = \pi\mu(R^4 - r^4)/2L$ , where  $r$  and  $R$  are the inner and outer radii respectively, and  $L$  is the length<sup>28</sup>. Using  $R = 70$  Å and  $r = 30$  Å, corresponding to the radii of maximum (rod) density and of the inner hole, respectively, for filaments of *Salmonella typhimurium*<sup>20</sup>, and our values of  $L = 0.2$  μm and  $k_\theta = 4 \times 10^{-12}$  dyne-cm rad $^{-1}$ , we obtain  $\mu = 2 \times 10^9$  dyne cm $^{-2}$ , which is 3–4 orders of magnitude lower than an estimate<sup>19</sup> ( $10^{11}$ – $10^{12}$  dyne cm $^{-2}$ ) derived from filaments of *S. typhimurium* that had been polymerized *in vitro*, but comparable to an estimate<sup>16</sup> ( $\sim 10^9$  dyne cm $^{-2}$ ) that was based on noise analysis of tethered *E. coli*. An explanation for this discrepancy could be that there is an additional compliance in flagella that is not present in filaments (see text and ref. 19). We note that the torsion constant attained by *E. coli* flagella at large angles is at least  $1 \times 10^{-10}$  dyne-cm rad $^{-1}$ , implying that  $\mu \geq 5 \times 10^9$  dyne cm $^{-2}$ .

These lengths range from 0.1–0.5 μm, as estimated from the lateral displacements of cells that occur during normal reversals, or when cells are moved sideways with the optical trap. We note that both curves for *E. coli* in Fig. 4 are nearly superimposable when normalized to the maximum angle.

What is the explanation for the shape of the compliance curve? One possibility is that flagellar compliance consists of two distinct components: a 'soft' initial phase resulting from twisting of the proximal hook, and a 'hard' terminal phase dominated by the filament once the hook has reached some elastic limit. Published estimates of the flexural and torsional rigidity of isolated filaments<sup>18,19</sup> indicate that they are far stiffer than our values of  $k_\theta$  would imply (compare Fig. 4). It is also possible that the compliance is entirely dominated by the filament itself and that it is intrinsically nonlinear. A 0.2 μm-long tether carries roughly 80 turns of the lowest-order helical lattice, which has a pitch close to 26 Å and an outer diameter close to 200 Å (ref. 20). Twisting such a filament through one-half revolution would impose more than  $2^\circ$  of superhelical twist (shear) per turn, requiring a substantial accommodation of the structure. These possibilities could be distinguished by measuring the elastic properties of polyhook strains, which produce abnormally long hooks<sup>21</sup>, and/or by making compliance measurements over a wide range of filament lengths. We do not believe that the compliance is due to, say, elasticity of force generators which link the rotor to the cell wall, because DNP treatment also induced partial lock-up of  $\Delta(motA-motB)$  cells. In relaxation experiments, these cells rebounded like wild-type cells. We did not see any abrupt changes in compliance which might be attributable to polymorphic transitions in the filament, even though the torques exceeded those experienced by flagella in tumbling cells, where such interconversions have been observed<sup>6</sup>. It is possible that interconversions did occur but remained undetected because of the shortness of the tethers, which are only a fraction of the normal flagellar wavelength. It is also possible that anti-filament antibody bound to the tether or tight association with the surface at the filament's distal tip prevented such cooperative transitions.

This elastic nonlinearity could be useful in motility. The filaments need to be stiff to function efficiently as propellers. But to form a coherent bundle, flagella emerging from distinct motors distributed over all parts of the cell body must coalesce, with attendant distortion of their helical geometry<sup>22</sup>. Early events in bundle formation may take advantage of a relatively soft (hook-based?) compliance to stabilize the coordinated bundle. We note that the torque produced by motors in actively swimming *Streptococcus* ( $\sim 1 \times 10^{-11}$  dyne cm $^{10}$ ) is just sufficient to wind flagella beyond the linear compliance domain.

Optical tweezers provide a novel means of measuring the elastic properties of individual bacterial flagella, means that are hard to duplicate with conventional techniques, for example, those using thin glass needles<sup>23</sup>. We anticipate that trapping technology will be applicable to the manipulation of a wide range of macromolecular assemblies. □

‡ To whom correspondence should be addressed.

**BLOOD** coagulation can be initiated when factor VII or VIIa, a plasma protease, binds to its essential cofactor, tissue factor (TF), and proteolytically activates factors IX and X<sup>1,2</sup>, triggering a cascade of events which eventually leads to the formation of thrombin and a fibrin clot. Plasma contains a lipoprotein-associated coagulation inhibitor (LACI) which inhibits activated factor X (Xa) directly and, in a Xa-dependent way, inhibits VII(a)/TF

activity, presumably by forming a quaternary Xa/LACI/VII(a)/TF complex<sup>3-5</sup>. Sequence analysis of complementary DNA clones has shown that LACI contains three tandemly repeated Kunitz-type serine protease inhibitory domains<sup>6,7</sup>. To investigate the relationship between these Kunitz structures and LACI function, we have used site-directed mutagenesis to produce altered forms of LACI in which the residue at the active-site cleft of each Kunitz domain has been individually changed. The second Kunitz domain is required for efficient binding and inhibition of Xa, and both Kunitz domains 1 and 2 are required for the inhibition of VIIa/TF activity; but alteration of the active-site residue of the third Kunitz domain has no significant effect on either function. We propose that in the putative inhibitory complex, Kunitz domain 1 is bound to the active site of VII(a)/TF and that Kunitz domain 2 is bound to Xa's active site.

Bovine pancreatic trypsin inhibitor (BPTI, aprotinin) is the best characterized Kunitz-type inhibitor and alteration of the residue in the P1 position<sup>8</sup> of the active-site cleft of BPTI profoundly alters its inhibitory activity<sup>9</sup>. By sequence homology alignment with BPTI, the P1 position for each of LACI's Kunitz domains was identified (ref. 6; Fig. 1). We used site-directed mutagenesis to prepare LACI mutants in which this active-site-cleft residue in each Kunitz domain has been individually changed. Thus, the mutants were designed to maximize the effect on each domain's function while minimizing the possible alteration in the protein structure. These modified LACI DNAs were introduced into the bovine papilloma virus vector pMON1123 and cotransfected with pSV2neo into mouse C127 fibroblasts.

FIG. 1 *a*, Schematic diagram of LACI's predicted secondary structure showing the sulphhydryl bonding for the three Kunitz domains. The Kunitz domains are numbered from the one closest to the N terminus. The arrows indicate the location of the presumed P1 residues of the active-site clefts for the Kunitz domains<sup>8,9</sup>. The charges of the amino-acid side chains are indicated (histidine side chains are considered as uncharged). Asterisks show the potential sites for N-linked glycosylation. *b*, Western blot showing the expression of the recombinant wild-type and mutant LACIs. Serum-free conditioned media (100  $\mu$ l) from the indicated cells and 20 ng purified LACI(hepG2) were run on a 15% polyacrylamide gel, transferred to nitrocellulose, probed with mouse polyclonal anti-LACI antibodies and colourimetrically developed<sup>7,10</sup>. Relative molecular masses are shown on the left in thousands.

**METHODS.** A modified LACI cDNA insert engineered into a bovine papilloma virus vector for expression in C127 fibroblasts<sup>7</sup> was ligated into M13mp18 and site-directed mutagenesis<sup>11</sup> was performed as follows (the numbering of nucleotides and amino acids is according to the 4.0 kilobase (kb) LACI cDNA sequence<sup>7</sup>. LACI(Ile 36): A  $\rightarrow$  T at 572 which changes Lys 36 to Ile. LACI(Leu 107) G  $\rightarrow$  T at 785 which changes Arg 107 to Leu. LACI(Leu 199): G  $\rightarrow$  T at 1,061 which changes Arg 199 to Leu. Sequences of the mutant molecules were confirmed by the dideoxy chain-termination procedure<sup>12</sup> and cloned into the bovine papilloma virus expression vector pMON1123 (ref. 7). Each of these expression vectors plus pSV2neo were cotransfected into mouse C127 fibroblasts using calcium phosphate precipitation<sup>3</sup> and G418-resistant clones were screened for expression of LACI. LACI(hepG2) was purified as previously described<sup>14</sup>.

FIG. 2 Binding and inhibition of factor Xa by wild-type and mutant LACIs. Factor Xa inhibitory activities were determined as previously described<sup>3</sup> using 25 ng ml<sup>-1</sup> (final concentration) bovine factor Xa. Samples are: LACI(hepG2) (○); LACI(wt) (●); LACI(Ile 36) (▲); LACI(Leu 107) (▼); LACI(Leu 199) (◆). Inset, <sup>125</sup>I-labelled Xa blot analysis of LACI mutants. Samples are designated in the same way as in Fig. 1.

**METHODS.** LACIs were precipitated from transfected cell clones' serum-free conditioned media using CdCl<sub>2</sub>, resuspended in 0.25 M EDTA, pH 9.0, clarified and dialysed into 0.1 M NaCl, 0.05 M Tris-HCl, pH 7.5 (TS buffer)<sup>14</sup>. Recombinant LACIs were purified using a mouse monoclonal anti-LACI-affigel 10 column. Dialysed CdCl<sub>2</sub>-concentrated LACI samples were applied to the column in TS, the column was washed with several volumes of TS and LACI was eluted with 2 M NaSCN. After the addition of BSA as carrier, concentration and dialyses into TS, the LACI concentration for each sample was determined in a particle-concentration immunofluorescence assay<sup>15</sup> using two non-competitive anti-LACI monoclonal antibodies. For the ligand blot, 50 ng of each sample was electrophoretically fractionated by SDS-PAGE, transferred to nitrocellulose, and then probed with <sup>125</sup>I-labelled Xa (refs 7, 10). Western blot analysis using rabbit polyclonal anti-LACI antibodies was performed on a duplicate blot to confirm that equivalent amounts of LACI were present in each sample (data not shown).

FIG. 3 VII(a)/TF inhibitory activities of the wild-type and mutant LACIs measured by a [<sup>3</sup>H] IX activation peptide release assay (a) and a three-stage clotting assay (b). Both assays were performed as previously described<sup>3,7</sup> with LACI(hepG2) (○); LACI(wt) (●); LACI(Ile 36) (▲); LACI(Leu 107) (▼); LACI(Leu 199) (◆).

Individual clones expressing human LACI messenger RNA (data not shown) and LACI protein were identified (Fig. 1) and recombinant LACIs were isolated from the clones' conditioned media using monoclonal anti-LACI affinity chromatography.

LACI isolated from the conditioned media of a human hepatoma cell line (hepG2), as well as that isolated from plasma, bind <sup>125</sup>I-labelled factor Xa on ligand blots and inhibit the enzymatic activity of factor Xa (refs 3 and 10; W.F.N. *et al.*, manuscript submitted). We assessed the ability of the modified LACI molecules to bind to and inhibit factor Xa. LACI(Ile 36) and LACI(Leu 199) with an altered active-site residue for Kunitz domains 1 and 3, respectively, both bound <sup>125</sup>I-labelled Xa on ligand blots and inhibited factor Xa to the same degree as recombinant wild-type LACI LACI(wt) or LACI(hepG2). But LACI(Leu 107), which contains an altered active-site residue in the second Kunitz domain, was not recognized by <sup>125</sup>I-labelled Xa, nor did it inhibit factor Xa (Fig. 2). These results indicate that the second Kunitz domain is responsible for the binding to, and inhibition of, factor Xa by LACI.

The ability of the altered LACI molecules to inhibit VII(a)/TF activity in the presence of Xa was determined using two separate assays. In the first, VII(a)/TF activity was determined by the release of the activation peptide from its substrate factor IX (ref. 7). LACI(Leu 199), which contains an altered Kunitz domain 3, inhibited the VII(a)/TF activity to the same degree as LACI(wt) and LACI(hepG2) (Fig. 3). Modification of either the first Kunitz domain, LACI(Ile 36), or the second Kunitz domain, LACI(Leu 107), did result, however, in the loss of VII(a)/TF inhibitory activity.

Similar results were obtained for the mutant proteins in a three-stage clotting assay which is dependent on VII(a)/TF activation of its other substrate, factor X. In this assay, inhibition of VII(a)/TF activity by LACI depends on the presence of factor X (which is converted to Xa) in the first stage of the assay<sup>3</sup>. Inhibition of VII(a)/TF activity in the first stage causes less factor X to be activated in the second stage, so clotting takes a

FIG. 4 Schematic diagram of the proposed mechanism for the inhibition of factor Xa and the VII(a)/TF complex by LACI. VII(a) denotes either VII or VIIa; the indentations represent the active sites for VII(a) and Xa; and the protrusions represent the three Kunitz domains of LACI. In the Xa/LACI complex, the active site of Xa is bound to the second Kunitz domain of LACI. In the final quaternary Xa/LACI/VII(a)/TF complex Xa is bound at its active site to LACI's second Kunitz domain and VII(a) is bound at its active site to the first Kunitz domain of LACI. The mechanism of the association of LACI with lipoproteins is not known.

longer time. Again, mutation of the active-site residue in either the first or second Kunitz domain abrogated LACI's ability to inhibit VII(a)/TF activity effectively, whereas mutation of the third Kunitz domain had no effect on activity. At high concentrations of LACI(Leu 107) a slight but reproducible inhibition was observed (Fig. 3). This low level of inhibition was also dependent on the presence of Xa in the first stage of the assay (data not shown).

Our current working hypothesis for the mechanism by which LACI inhibits VII(a)/TF activity is schematically shown in Fig. 4. When plasma is exposed to TF, VII(a) binds to TF and activates factors IX and X. Some of the Xa generated becomes bound by its active site to LACI's second Kunitz domain and is inhibited. This Xa/LACI complex then binds to, and inhibits, the VII(a)/TF complex, presumably by forming a Xa/LACI/VII(a)/TF quaternary complex. Alternatively, LACI may bind to a preformed VII(a)/TF/Xa complex<sup>3</sup>. We have previously shown that the N-terminal domain of Xa, containing its  $\gamma$ -carboxyglutamic acids which are required for  $\text{Ca}^{2+}$  binding, is necessary for inhibition of VII(a)/TF activity by the LACI/Xa complex<sup>3</sup>. The results presented here indicate that the second Kunitz domain is necessary for the formation of the Xa/LACI complex; this, and also the first Kunitz domain, are required for VII(a)/TF inhibition. The effect of domain 1 is presumably

mediated through its binding to the active site of VII(a). The native P1, residue of LACI's third Kunitz domain, however, does not seem to be required for these functions. It is conceivable that changing Arg 199 to Leu was not sufficient to affect functional activity of the third domain, or that a portion of the domain unrelated to its active-site cleft is required for function, but we believe that both these possibilities are unlikely.  $\square$

## Conformational dynamics of individual DNA molecules during gel electrophoresis

David C. Schwartz & Michael Koval

Carnegie Institution of Washington, Department of Embryology,  
115 West University Parkway, Baltimore, Maryland 21210, USA

GEL electrophoresis is widely used in molecular biology to separate DNA molecules according to their sizes. The physical basis of this size separation is, however, poorly understood. Here we report observations of individual, fluorescently stained DNA molecules as they migrate during various kinds of gel electrophoresis. Their movement, under the influence of either a steady electric field or a pulsed-field, is characterized by cycles of elongation and contraction. Initially relaxed coils of DNA lengthen into 'hook-shaped' configurations which temporarily 'hang-up' on obstacles in the gel matrix before sliding off, contracting and entering another cycle. The effects of a new electrophoresis technique, termed 'pulse-oriented electrophoresis', which allows the effective angle of the electric field, and hence the molecular orientation of DNA, to be varied without electrode rearrangement, are also studied. In this case the DNA adopts a 'staircase' configuration showing that the net orientation in a direction is given by the vector sum of the pulses used.

Individual DNA molecules undergoing conventional gel electrophoresis were visualized using a microscope-mounted miniature electrophoresis apparatus. As shown in Fig. 1a-f, molecules initially in a random conformation elongated to form 'hook' structures which aligned with the applied electric field and 'wrapped around' obstacles in the gel. Tension between the two arms of a hook was resolved when one arm became dominant (Fig. 1d, e; molecule 1), pulling the other arm past the obstacle and facilitating coil relaxation to a more random conformation. Recurring cycles of elongation, resolution and relaxation were observed for the duration of the applied steady field. Collectively, these orientational events confirm previously published models<sup>3-6</sup>. The application of a second electric field, oriented at 90° to the first, resulted in a realignment of DNA molecules (Fig. 1g-i). Immediately after field switching, segments of all

molecules began to move in the direction of the new field, and after 39 s, most of the molecules assumed hook structures that were somewhat broader than those found in the steady field case.

Separation by pulse-field electrophoresis depends on the angle between successively applied fields (field angle)<sup>7-11</sup>, with obtuse angles providing superior separation of large DNA molecules. A new electrophoretic effect and its associated method, pulse oriented electrophoresis (POE), was thus used to study the relationship between field angle and DNA conformational changes.

POE has been used to resolve the chromosomes of both *Saccharomyces cerevisiae* and *Schizosaccharomyces pombe* in a manner analogous to the pulse electrophoretic method<sup>12</sup>. Briefly, POE allows molecular orientation to be varied, without the requirement of electrode rearrangement, by using a series of alternating perpendicular pulses shorter than the orientation time for a given molecule. These pulses are applied such that their predicted effect is to fold a DNA molecule into a staircase-like configuration<sup>9</sup>. The net alignment of each rapidly pulsed molecule is then the vector sum of the DNA segmental orientations corresponding to the 'steps' of the staircase. This alignment can be altered by varying the pulse duration ratio of the two perpendicular fields. Thus, POE emulation of pulse-field electrophoresis using a 90° field angle (Fig. 2a-f) caused molecules to adopt the predicted 'staircase' conformation and exhibit coil dynamics similar to those shown in Fig. 1.

The emulation of an obtuse field angle (~120°) by POE (Fig. 3) resulted in molecules elongating to form broad hooks which also exhibited the staircase effect. These structures collapsed within 6 s of switching fields, whereas roughly 20 s were required for collapse after a 90° field switch (Fig. 2); the apparent coil relaxation time after electric field cessation, however, was about 60 seconds (Fig. 4).

Our results suggest a model for the field-angle-dependent reorientation mechanism of POE that might also apply to pulse-field electrophoresis. Consider the electric field force components generated along a stretched DNA coil axis (constrained by the gel matrix) immediately after the field direction has shifted. If the field angle is 90°, then, on average, both ends of an extended coil will be equally favoured to move in the direction of the new electric field and this inhibits coil relaxation. If the field angle is obtuse, however, then the new electric field will have a component parallel to the elongated coil axis which can

FIG. 1 G bacteriophage DNA molecules, 700 kilobases (kb) long, stained with 4,6-diamidino-2-phenylindole (DAPI) visualized during gel electrophoresis. The images were obtained at 0 s (a), 5 s (b), 16 s (c), 28 s (d), 33 s (e), 44 s (f), 54 s (g), 60 s (h) and 93 s (i) after field initiation. a, The apparent radius of relaxed G bacteriophage DNA (see arrowheads) in a 1.0% low-melting-temperature gel matrix; this was similar to the solution value of  $2.2 \times 10^{-4}$  cm. b, The effect of a uniform electric field ( $3.5 \text{ V cm}^{-1}$ ); the coils move and elongate in the direction of the applied field (arrow). b–f, The continuing movement produces a series of hook structures and thick rod-like coil conformations. g–i, The effect of shifting the field direction by  $90^\circ$  (arrow); the molecules reorient. Bar; 10  $\mu\text{m}$ .

**METHODS.** G bacteriophage was grown as previously described<sup>14</sup>. DNA was prepared by lysing virus in  $1/2 \times \text{TBE}$  buffer (42.5 mM Trizma base, 44.5 mM boric acid, 1.25 mM disodium EDTA) followed by ethanol precipitation; this did not shear the sample. DNA in  $1/2 \times \text{TBE}$  was diluted to  $0.1\text{--}0.2 \text{ ng ml}^{-1}$  in prefiltered 1.0% low-gelling-temperature agarose (Sea Plaque) in  $1/2 \times \text{TBE}$ ,  $0.3 \mu\text{g ml}^{-1}$  DAPI (Sigma), 1.0% 2-mercaptoethanol and held at  $65^\circ\text{C}$ . Samples were mounted using  $3 \mu\text{l}$  DNA-agarose mixture, transferred to a preheated slide, covered, then placed

into a miniature pulse electrophoresis apparatus consisting of a series of discrete platinum electrodes surrounding the square cover slip, wetted with agarose for contact, and connected to diodes to prevent electrode-generated field distortion effects. Samples were pre-electrophoresed for 2–3 min and allowed to relax at room temperature before observation. Field strength was measured using auxiliary electrodes connected to a multimeter. A

Zeiss Axioplan microscope and a C2400-SIT camera (Hamamatsu Corp.) were used with low level excitation light to minimize photodamage during imaging. For each image, eight video frames were digitized, boxcar-averaged and corrected to remove background fluorescence using an IC-1 image processing system (Inovision Corp.).

FIG. 2 Bacteriophage G DNA using POE conditions analogous to those for pulse field electrophoresis with a  $90^\circ$  field angle (3, 3–84 s at  $3.5 \text{ V cm}^{-1}$ ; see Methods), followed by field reversal (continuous field;  $3.5 \text{ V cm}^{-1}$ ). a–f, Images obtained at 570 s (a), 600 s (b), 612 s (105 after field switch) (c), 624 s (d), 672 s (e), and 836 s (f) after POE-field initiation. g–j, Images obtained at 2 s (g), 6 s (h), 12 s (i) and 18 s (j) after field reversal. a, The trapped molecule (1) joined by other coils moving into the field from the bottom; b, the newly arrived coils display conformations including hooks and condensed coils. c, After the field switch (arrows), hooks resolve into single strands terminated with a dense region. The newly entangled coil (2) undergoes considerable conformational change from a thick rod (a), to a

stubby hook (b), to a round, dense mass (c). The two trapped coils (d–f) show the 'staircase' effect characteristic of POE. g–j, Pulsing ends and a reversing field is applied, which rapidly unhooks, disentangles and collapses both molecules. Scale bar, 10  $\mu\text{m}$ .

**METHODS.** Microscopy and sample preparation methods are described in Fig. 1. POE utilized a series of short, alternating perpendicular pulses. After a period of time, the polarity of one of the fields was switched. 3, 3–84 s describes a cycle, alternating between a 3 s pulse east–west and a 3 s pulse south–north with an 84 s duration, followed by another 84 s cycle alternating between a 3 s pulse east–west and a 3 s pulse north–south and so on.

FIG. 3 G bacteriophage DNA electrophoresis with POE conditions emulating an obtuse field angle; 6, 10–80 s, at  $3 \text{ V cm}^{-1}$ . *a–h*, Images obtained 0 s (*a*), 18 s (*b*), 85 s (3 s after field switch) (*c*), 120 s (*d*), 138 s (*e*), 158 s (*f*), 165 s (5 s after field switch) (*g*) and 171 s (*h*) after POE-field initiation. Changes in field orientation are shown by arrows (*b, c, g*). Molecules begin from a

relaxed conformation (*a*) and elongate to a 'staircase' conformation characteristic of POE as the pulsing proceeds (*b–h*). Inversion of the hooks also occurs (*c–e*; arrowhead). Scale bar,  $10 \mu\text{m}$ . Sample preparation and experimental conditions were as described in Figs 1 and 2.

FIG. 4 Relaxation of G bacteriophage DNA molecules in the absence of an electric field. Molecules were initially electrophoresed for 600 s (POE conditions; 3, 5–80 s,  $3 \text{ V cm}^{-1}$ ). Images, obtained at 12 s intervals, show the relaxation of several molecules over a 111-s time span. *a*, 3 s after turning off the applied field. The coils (arrowheads) relax through the same 'staircase'

path that was induced by the applied electrical pulses (as determined by the limits of microscopic resolution). *c*, Note that either one molecule (molecule 2) has fragmented or two molecules have separated. *j*, All coils have relaxed to a round, unelongated conformation. Scale bar,  $10 \mu\text{m}$ . Sample preparation and experimental conditions were as described in Figs 1 and 2.

augment coil relaxation in that direction (in hooks, this is towards the apex). Additionally, the coil ends may not be equivalent, which may also bias motion in both perpendicular and obtuse field situations.

Despite the low sample concentrations used in the electrophoresis experiments, DNA-DNA interactions were also observed. Figure 2, for example, shows a temporarily immobilized DNA molecule (molecule 1) trapping another DNA molecule. Reversal of the electric field ( $180^\circ$  field shift) released both molecules and caused the rapid collapse and eventual

reformation of the hooks. It is probable that similar events occur in reverse-field electrophoresis and this is, indeed, the conclusion of several computer simulations<sup>3,4,6</sup> and spectroscopic studies<sup>13</sup>.

These results show that static-field, pulse-field and pulse-oriented electrophoresis give rise to similar cycles of DNA conformational changes that include hook formation, resolution, collapse and re-formation. Furthermore, it seems that the field angle has a pronounced effect on DNA coil dynamics with perpendicular field angles preventing the rapid collapse of structure after field switching. □

## GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously.

*Nature* is an international journal covering all the sciences. Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields. Please write clearly and simply, avoiding unnecessary technical terminology. *Nature's* staff will edit manuscripts to those ends if necessary. Contributors should check their proofs carefully. Because of the competition for space, many of the papers submitted for publication cannot be accepted. For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility. Please note that one printed page of *Nature*, with-out diagrams or other interruptions of the text, has fewer than 1,300 words.

### CATEGORIES OF PAPER

**Review Articles** survey recent developments in a field. Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator. Length is negotiable in advance but must not exceed six pages of *Nature*.

**Articles** are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding. They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*.

Articles should be accompanied by a heading of 50–80 words written to advertise their contents in general terms, to which editors will pay particular attention. A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements. The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications. Articles may contain a few subheadings of two or three words. The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows. There should be fewer than 50 references.

**Letters to *Nature*** are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field. Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature*. The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study. Letters should not have subheadings or more than 30 references.

**Commentary** articles deal with issues in, or arising from, research that are also of interest to readers outside research. Some are commissioned, most are unsolicited. They are normally between one and four pages of *Nature* in length.

**News and Views** articles are intended to inform non-specialist readers about a recently published advance. Suggestions should be made to the News and Views Editor. Illustrations are welcome. Proposals for meeting reports should be agreed in advance.

**Scientific Correspondence** is for the discussion of scientific matters, including contributions published in *Nature*. Priority is given to contributions of less than 500 words and five references. Figures are welcome.

**Submission.** All manuscripts may be submitted to either London or Washington. They should not be addressed to editors by name. Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value \$5' to prevent the imposition of import duty and value-added tax (VAT).

### GENERAL

All contributions submitted for publication in *Nature* should conform with these rules.

**Manuscripts** should be typed, double-spaced, with a good-quality printer, on one side of the paper only. Four copies are required, each accompanied by lettered artwork. Four copies of half-tones should be included. Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered. Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such. Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers.

**Titles** should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters. Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes.

**Artwork** should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number. Original artwork should be unlettered. Ideally, no figure should be larger than 28 by 22 cm. Figures with several parts are permitted only if the parts are closely related, either experimentally or logically. Suggestions for cover illustrations, with captions, are welcome. Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published.

**Colour Artwork.** A charge of £500 a page is made for 4-colour figures. Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained.

**Figure legends** must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible. The figure should be described first, then, briefly, the method. Reference to a method described elsewhere is preferable to a full description. Methods should not be described in detail in the text.

**References** should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends. Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited. All other forms of reference (including unreferenced abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate). Text should not be included in the reference list. References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963–65). The first and last page numbers should be cited. Reference to books should clearly indicate the publisher and the date and place of publication.

**Abbreviations,** symbols, units and Greek letters should be identified the first time they are used. Acronyms should be avoided as much as possible and, when used, defined. Editors will shorten words if necessary. In case of doubt, SI units should be used.

**Footnotes** should not be used except for changed addresses or to identify the corresponding author if different from the first named.

**Acknowledgements** should be brief. Grant numbers and contribution numbers are not allowed.

# THE PERFECT BIND

When did *Nature* cover Science in Switzerland?

Where are the latest research results about AIDS?

What's the latest development in superconductivity?

Have you noticed that you never manage to lay your hands on that issue of *Nature* when you need it most!

For a very reasonable cost, why don't you save time and effort by investing in a set of smart and durable *Nature* binders.

	Single binder	Set of 4	
UK	£5.25	£16.00	Prices include
Rest of World	£7.75	£22.00	postage and packing

Never again will you be at a loss for that vital information. Each binder holds approximately 16 issues and makes sure that key knowledge is kept at your fingertips.

Complete the order form and in no time your copies of *Nature* can be kept in order.

Please send me \_\_\_\_\_ *Nature* binders Name \_\_\_\_\_

☐ I enclose a cheque for £ \_\_\_\_\_ Address \_\_\_\_\_  
made payable to *Nature*

☐ Please charge my credit card for £ \_\_\_\_\_  
☐ Visa ☐ AMEX ☐ Access

Return to: Mary Long, *Nature*, Brunel Road, Basingstoke, Hants, RG21 2XS, UK. Please allow 28 days for delivery in the UK and longer for the rest of the world.

THE MOST EFFICIENT SYSTEM TO CROSSLINK DNA TO MEMBRANES.

# FLUO-LINK 312

**"By increasing reproducibility and sensitivity of your nucleic acid blots on membranes, you will save time".**

**2 FUNCTIONS:**

- DNA fixation in less than 2 minutes
- visualization of electrophoresis gels

Hybond™ - N nylon membrane.

0.25 µg of DNA transfer of  $\lambda$  digested by Hind III and hybridized at  $\lambda$ -marked Hind III.

- 1 - 0,30 joules (0'45")
- 2 - 0,41 joules (1'00")
- 3 - 0,51 joules (1'15")
- 4 - 0,60 joules (1'30")

Optional: FLUO-LINK can be equipped with 254 or 365 nm tubes.

## Time saving

To fix nucleic acids to membranes, the traditional method consists in baking the membranes for two hours at 80°C. FLUO-LINK 312 requires only a few minutes UV 312 nm irradiation.

## Improvement of the signal intensity

The hybridization signal resulting from UV irradiation is 5 to 10 times higher than with traditional baking (1) (2).

## Reproducibility

FLUO-LINK is equipped with a UV energy programming system (in joules/cm<sup>2</sup>) with a time integrator which constantly monitors the UV light emission.

The irradiation stops automatically when the energy received matches the programmed energy. Therefore, irradiation cycles are perfectly reproducible whatever the UV source intensity and variation in time.

Reader Service No.7

# Springtime launches for the lab

The spring of the year brings a flurry of product introductions: this season's best includes a phenol-free DNA extraction kit, an LC/MS that can handle haemoglobin, and a benchtop robot that does the drudge jobs without complaint.

SIGMA Chemical Company recently announced a special line of highly purified synthetic oligosaccharides and derivative

Bioactive carbohydrates from Sigma Chemical. fragments of biologically active glycoconjugates (*Reader Service No. 100*). The complex **bioactive carbohydrates** have applications in diverse areas of medical and biological research, including substrate specificity studies of glycosidases and glycotransferases, and studies of drug targeting, cell proliferation and oncogenesis. They may also be used as model compounds for the study of complex carbohydrates by NMR spectroscopy, and can be incorporated into liposomes.

Jeol's new model JEM 1200 EXII **electron microscope** was developed specifically to support fundamental biotechnology research and environmental studies involving particle microanalysis (*Reader Service No. 101*). The microscope has a three-stage, six-lens image-forming system, which Jeol says provides high resolution, a wide visual field, low image

Jeol's new transmission electron microscope has a wide magnification range.

distortion and high-contrast image quality at low magnifications. The TEM has a magnification range of 50–1,000,000 ×, and a focus zoom which allows magnification changes without focus changes. Samples may also be measured quantitatively with Jeol's microscope: lengths, angles, and areas of the overall sample can be recorded, and lattice spacing and angles can be determined using diffraction patterns, down to a resolution of 0.14 nm.

Oncor says its new non-organic **DNA extraction kit** produces high-purity, high-yield DNA in four hours, without the use

No fussing with phenol is necessary with Oncor's non-organic DNA extraction kit.

of hazardous organic chemicals (*Reader Service No. 102*). The kit's reagents are qualified on human samples in Oncor's molecular pathology laboratory. The company says the kit provides DNA whose purity compares with phenol extraction: Oncor says the absorbance ratio ( $A_{260}/A_{280}$ ) of the purified DNA falls between 1.75 and 1.90. The kit eliminates the need for dialysis or extraction steps, cutting DNA purification time down from three days to roughly four hours, Oncor says. The proprietary reagents used in the \$150 (US) DNA extraction kit are non-caustic and non-carcinogenic, and can be poured safely down laboratory drains.

## The computing edge

PolyView is the name of a new software system from Varian which aims to make **diode array spectral processing** for liquid chromatography more productive (*Reader Service No. 103*). The PolyView software is designed to work with the Polychrom 9065 diode array detector, as a part of a complete \$23,000 (US) system built around the PC-based LC Star chromato-

PolyView chromatogram analysis software.

graphy workstation. With the Microsoft Windows environment of PolyView, chromatographers can take data from an information-rich detector, and present it in a variety of diverse formats simultaneously on one computer screen. The software has a bidirectional library function: users can search the library for a chromatogram that matches peaks from one obtained experimentally, or search a given chromatogram for similarities to a library standard. Reports are printed automatically at the end of each run. PolyView also calculates Varian's Purity Parameter — the average wavelength weighted by the square of the absorbance — to help chromatographers locate impurities.

Mathor 3, the **technical word processing software** from Novedit, displays scientific formulae and mathematical equations on the computer screen as they will appear in printed form (*Reader Service No. 104*). The software automatically draws and sizes all mathematical symbols, such as square root signs and integrals, to accommodate their contents. Formulas can be inserted on the same line as text, and frequently used mathematical expressions can be stored in Mathor 3's memory to be inserted at the touch of a key. Mathor 3 has five character sets, including the full Greek alphabet, operators and logical symbols, and common physics and mathematics characters. Text may be imported to Mathor 3 from Word and WordPerfect word-processing programs. The FF3,000 (France) Mathor 3 software runs on IBM PC and PS/2 computers equipped with a graphics adaptor card.

The LabSolutions program from The Center for Science Support, Inc. automatically performs the necessary calculations for preparing multi-component solutions and buffers (*Reader Service No. 105*). The \$99 (US) **solution calculation software** uses standard units of weight,

volume, and concentration, and calculates molecular weights from atomic formulas or chemical names. Solution recipes can be stored on disk for retrieval, and printed out for documentation purposes. Specialized routines for mixing and diluting solutions, and for automatically generating linear and geometric dilution series are also included. Users may add their own entries to the built-in databases of chemicals, buffers, acids and bases. The LabSolutions user manual includes chapters on choosing the best buffer, deriving titration equations, and adjusting the pH. LabSolutions is available on 3.5-in. and 5.25-in. diskettes for IBM PCs; a Macintosh version will be released soon.

## Popular culture

Laboratory Impex Ltd has a **Mycoplasma detection kit** which it says sniffs out the presence of as little as  $10^3$  organisms contaminating a tissue culture in just three hours (*Reader Service No. 106*). The company's Gen-Probe Mycoplasma TC detection system employs the principle of nucleic acid hybridization: the kit contains a  $^3\text{H}$ -labelled DNA probe homologous to Mycoplasma and Acholeplasma ribosomal RNA. Laboratory Impex says the probe detects all species which commonly infect tissue cultures. Incubating the hybridization reaction for 15–20 hours increases the sensitivity of the test three to five times, according to the company.

Baxter Healthcare Corporation has a flexible, 25-litre **recovery container** designed to replace carboys and stainless steel tanks in large-scale cell culture (*Reader Service No. 107*). The Lifecell container is composed of several layers of non-toxic, gas-barrier plastic which Baxter says offers stability equivalent to that of glass. The containers require minimal storage space, and can be stacked in tote pans when filled. Baxter says the container is lined with a layer of polyolefin which is non-reactive with biologicals. Two separate tubes with Luer connection ports are attached to the container to facilitate filling and emptying procedures.

## Gel gems

Bio-Rad's roundup of electrophoresis products includes **pipette tips for gel loading** and a **reagent and sample preparation**

Bio-Rad's kit for readying samples and reagents for electrophoresis.

Bio-Rad's Gel-Loader.

kit (*Reader Service No. 108*). Bio-Rad's Gel Loader disposable capillary pipette tips have a non-wetting surface which delivers samples of between 0.5 and 10  $\mu\text{l}$ . The capillary of each tip is less than 0.35 mm o.d., making them useful for loading 0.25-mm sequencing gels. The 15-mm capillary reaches to the bottom of each well in a gel, eliminating cross-contamination between lanes. Before wielding the pipette, Bio-Rad recommends cleaning up both samples and reagents with its kit which contains all of the materials needed to remove Triton X-100 detergent and SDS from samples, to concentrate 0.5–1.5-ml samples, and to deionize impure urea, formamide, glyoxal or acrylamide. Bio-Rad says use of the kit can prevent band broadening and reduce background levels.

The FisherBiotech division of Fisher Scientific has a new line of **autoradiography cassettes** for developing and intensifying

Protective cassettes for autorads from Fisher.

autoradiographs from electrophoretic gels (*Reader Service No. 109*). The cassettes come in sizes of 8 × 10 inches, 14 × 17 inches and 14 × 36 inches. All have stainless-steel frames and felt liners to prevent light leakage and ensure optimal contact between film and screen. The doors of the cassettes have integral locking bars, and Fisher says the cassettes are virtually warp-proof. The 8 × 10-inch cassettes cost \$88 (US); \$96 (US) with screens.

## Probing analyses

Micron Separations, Inc. is giving away an application kit for reprobing its NitroPlus 2000 supported nitrocellulose membranes

Get a free sample of Micron Separations' supported membranes.

(*Reader Service No. 110*). The **free membrane reprobing kit** contains a sample of MSI's NitroPlus 2000 membrane, two newly developed techniques for reprobing the membrane, and detailed procedures for stripping and reprobing Northern and Southern blots up to six times. Micron Separations says 80–90 per cent of the signal from the target DNA or RNA is retained using the reprobing protocols, with 90–100 per cent of the probe being removed after each reprobing step.

BRL has a new system for simplifying and standardizing the procedure of **labelling DNA probes** with biotin by nick translation (*Reader Service No. 111*). BRL's BioNick labelling system generates small probes which range in size from roughly 50 to 500 base pairs. Because they are small enough to penetrate tissue easily, BRL says the probes are ideal for *in situ* hybridization. The BioNick system employs a new biotinylated nucleotide, biotin-14-dATP, which has a long, 14-atom linker arm that BRL says leaves enough room for streptavidin to bind for the identification of probe-target hybrids. The BioNick kit includes sufficient reagents for labelling 50  $\mu\text{g}$  of DNA: a 10 × dNTP mixture that contains biotin-14-dATP in optimal concentration, a 10 × enzyme solution, stop buffer, autoclaved water, a positive control DNA to monitor performance, and detailed instructions.

## Handy helpers

BioTherm Corporation has a \$2,990 (US) **thermal cycler** for performing enzymatic gene amplification and other variable-temperature protocols (*Reader Service No. 112*). BioTherm's BioOven has an open design which allows it to be used with microtitre plates, microcentrifuge tubes, and a variety of other sample containers.

Gene amplification is just one of many applications for the air-heated oven from BioTherm.

The BioOven uses air heat, eliminating water spills and the need for oil layering. BioTherm says the oven heats from ambient temperature to 100 °C in roughly one minute, with a temperature uniformity of 1 °C. The oven's built-in microprocessor allows six independent heating and holding cycles within a given routine; up to eight separate programs can be stored and recalled for later use.

The BenchMate **benchtop robot** from Zymark was designed to free researchers from performing the routine sample preparation tasks required in most laboratories (*Reader Service No. 113*). The BenchMate can be configured to dispense liquids, perform membrane filtrations and solid-phase extractions, and inject samples into an HPLC for analysis. Zymark's \$11,000–18,000 (US) robot takes up just 21.5 × 29.5 inches of bench space, and holds up to 200 standard-sized test tubes. Precision syringes with Zymark's 12-port valving technology dispense up to 10 ml of liquid; with the gravimetric confirmation option, an audit trail can be created to confirm all liquid deliveries by weight. The BenchMate is

Zymark's answer to monotonous lab procedures: BenchMate.

controlled by a 3.5-in diskette which contains a menu-driven operating system for building method files, and can be programmed by direct connection to an IBM PC.

### Analytical technology

Last month Finnigan MAT introduced a **benchtop GC/MS** system which combines complete spectrum separation with detection at the picogram level—the Ion Trap System 40 (*Reader Service No. 114*). The ITS 40 is targeted for the environmental and forensic/clinical markets, where low-level trace identification is important. The system consists of the Varian model 3400 gas chromatograph mounted on a single base plate with the Finnigan ion trap quadrupole mass spectrometer, and controlled by an integrated Compaq Deskpro computer running Finnigan MAT's proprietary software. Finnigan MAT says the

\$85,000 (US) ITS 40 system supports a full-spectrum acquisition rate of up to 10 spectra per second and a scan rate greater than 5,600  $\mu\text{s}^{-1}$ .

Dionex has the latest entrant onto the market of the hottest analytical technique of the year: capillary electrophoresis (*Reader Service No. 115*). The Dionex CES I **capillary electrophoresis** system has detectors for both UV/visible absorbance and fluorescence which are linked to the instrument by fibre optics, bringing the

The Dionex system for capillary electrophoresis.

detector closer to the column. The CES I's 40-place autosampler is capable of performing the three most popular injection methods: electromigration, gravity and pneumatic injection. An automatic rinse and refill buffer system allows buffers to be changed during runs, and ensures reproducible electrophoresis by using fresh buffers for each run, says Dionex. The spring-loaded design of the cell means that capillaries can be changed quickly. The \$37,500 (US) system is controlled by menu-driven software and a video display. Results are generated in a chromatography-like format, so the system can interface with any recorder or integrator.

Sciex has developed an LC/MS system especially for the needs of the biopharmaceutical industry (*Reader Service No. 116*). Sciex's API III joins HPLC together with tandem mass spectrometry, through an atmospheric pressure ionization interface that Sciex says outperforms fast-atom bombardment and thermospray ionization methods to allow femtomolar detection. The IonSpray interface desorbs ionic compounds in the solution eluting from the HPLC into the ionization source using field-assisted ion evaporation. The molecular ions are then transferred to the mass analyser through a nitrogen curtain gas. The \$395,000 (US) system can be used to glean sequence information from peptides, proteins and oligonucleotides with molecular weights of over 100,000. Sciex says the API III has been used successfully to analyse haemoglobin.

### Setting it straight

Contrary to an earlier description (see *Nature* 338, 94; 1989), the model 230A HPEC system from Applied Biosystems is not a capillary electrophoresis instrument.

Automated electrophoresis, not CZE.

HPEC stands for high-performance electrophoresis chromatograph: the model 230A HPEC is an automated micro-preparative gel electrophoresis system which isolates and quantifies proteins and DNA on a tube gel column using standard electrophoresis protocols (*Reader Service No. 117*). After detection, eluted compounds pass into an integral fraction collector. Applied Biosystems's newly launched analytical capillary electrophoresis system is model number 270A. □

These notes are compiled by Carol Ezzell from information provided by the manufacturers. To obtain further details about these products, use the reader service card bound inside the journal. Prices quoted are sometimes nominal, and apply only within the country indicated.

### ADVERTISEMENTS

#### LIPOSOMES

REPRODUCIBLE — HOMOGENEOUS —  
EXTREMELY RAPID

Our new LIPOSOMAT guarantees rapid (5ml within 60 minutes) preparation of uniformly sized unilamellar liposomes. Liposome size is selectable between 25 and ca. 600 nm diameter. Sample volume is normally 5–10ml or up to 200ml if used in combination with an additional instrument. Lipid concentration can be up to 300 mg/ml.

Reader Service No.46

# The impact of Europe's 1992

Richard Pearson

Business links between Europe and the United Kingdom are increasing and barriers to mobility of labour are coming down. There are new opportunities for both employers and individuals.

As the date for closer European integration draws near, increasing attention is being paid to the possible effects it may have on UK and other European labour markets. International companies are developing management teams which can work across international boundaries. Others are moving into overseas markets for the first time and having to build up a knowledge of local employment conditions and styles of operating. Yet other companies are expanding their recruitment market across national borders.

Individuals are also increasingly moving across borders as horizons of opportunity are broadened from the traditional North American and Commonwealth job markets (*Nature* 319, 84; 1986). For example, we have recently seen a significant inflow of veterinarians into the United Kingdom from Italy and other parts of Europe impacting on the job opportunities of UK graduates. Even those organizations operating solely within the United Kingdom, for example the universities, polytechnics and research institutes, are being affected as European recruiters target the UK labour market. Already Siemens,

a near-universal phenomenon, hitting for example France, Italy, the Netherlands and West Germany alike; in the latter case the downturn is as high as 45 per cent over a decade (see figure), with only Ireland having an expanding youth labour force. We see also a convergence across labour markets with common growth occupations at high skill levels and in the services sector, and declining opportunities for the unskilled and manual workers.

Because of differences in structure and content, comparisons of the numbers graduating have to be made with care. For example, while fewer students in the United Kingdom are enrolled in higher education pro rata to population size, the numbers graduating compare more favourably because of the lower drop-out rates, and although the United Kingdom does not compare so well in terms of engineering it does rather better in the sciences. In terms of the balance between supply and demand we see a segmented market in many countries with high levels of graduate unemployment in the Netherlands, Spain, West Germany, Italy and Ireland coexisting with shortages of engineers, information technology specialists, and business studies graduates.

So how easy will it be to recruit in Europe? The free mobility of labour in the Community means work permits are no longer a problem, although Portugal and Spain will not be included until 1993. Another change about to make itself felt is the mutual recognition of qualifications. Mutual recognition for pharmacists has recently been achieved, but only after 16 years of negotiations, and that for architects after 17 years. A more specific problem will be knowing where to go to recruit and being able to make judgements about the European graduates. For example, while in the United Kingdom the careers services actively help recruiters by 'selling' their graduates, in many parts of Europe such services are rare and in some cases direct recruitment is banned on campuses. In these cases use has to be made of more general national employment services. Recruitment is more usually carried out through personal links with academics, student work placements and direct advertising in the national newspapers and professional journals. Speculative applications from students are also much more common. In Italy, family and personal contacts are also important, factors reinforced by the much greater tendency of students to live at home and go to local

universities, a practice which is common in continental Europe. Living away from home seems to be peculiar to Britain and to students attending national, prestigious institutions in Europe. A further complication for the outside recruiter is the problem of judging the relative merits and qualities of institutions, for example, comparing Louvain with Berlin and Barcelona.

New employment strategies will also be required for the European graduate, who will typically be 4-5 years older than the UK equivalent and will have come from a broader-based, although still specialist, degree course. Different selection tests may be needed, certainly less reliance can be placed on extracurricular activities, which are far less common, and on academic references, which are not normally available on the continent. As most European graduates will be aged 26-28, because of their longer degree courses and national service, they are likely to be more mature and capable than the 21-year-old UK graduate. Initial jobs are therefore likely to be at a higher level in an organization. Induction and initial training needs are therefore also likely to be different, as will the starting salary. In part these differences help explain the discrepancies that are quoted between UK and European graduate starting salaries.

Many challenges face the British recruiter looking to Europe as a new recruitment source. At the same time European recruiters are starting to target the United Kingdom so we will not have exclusive use of the home market. Competition is likely to be greatest in the case of the extended engineering degrees, some of the applied sciences and business courses, particularly where students have a foreign language. Few European recruiters are interested in the generalist graduate. A dilemma for our careers services will be whether, in the interests of serving their prime customers, the students, they encourage and welcome European recruiters on to the campuses.

This increasing internationalization of business and labour markets will increase mobility both into and out of the United Kingdom. European recruitment is not, however, going to be an easy solution to UK shortages. The challenge for the 1990s will be to ensure that European integration offers new opportunities for individuals and employers and does not just mean a new brain drain.

Richard Pearson is at the Institute of Manpower Studies, Mantell Building, University of Sussex, Falmer, Brighton, BN1 9RF, UK.

Index of populations of 16-18-year-olds, taking 1980 as the baseline (index 100). Source: *International Science and Technology Update* (NSF, Washington, 1986).

Thompson and Philips are among the regular recruiters in the United Kingdom.

In the United Kingdom skill shortages are going to get worse, because the downturn in the number of young people entering the labour market over the next five years will be even more disruptive if the planned economic growth continues. So are things easier in Europe? The first point is that the demographic downturn is

## INSTITUTE OF VIROLOGY AND ENVIRONMENTAL MICROBIOLOGY (OXFORD)

### RESEARCH VACANCIES

## MICROBIAL GENETICS, MOLECULAR BIOLOGY AND MICROBIAL PLANT ECOLOGY

With the expansion of the remit of the NERC Institute of Virology to include environmental microbiology, and the change of the name to the INSTITUTE OF VIROLOGY AND ENVIRONMENTAL MICROBIOLOGY, a new program of research in environmental microbiology has been launched.

Three new staff appointments have been created, two at the post-doctoral, (HSO), level and one at the post-graduate, (SO), level. We are looking for highly motivated individuals, with experience in prokaryotic genetics and molecular biology who would be interested in developing a research career in this important area. Knowledge of microbial ecology would be an asset. The initial research objectives of the group include the quantification and study of the fate, transfer and persistence of genetically engineered bacteria and their DNA in the environment following release onto plant surfaces, thereby leading to an understanding of the potential risk and environmental impact.

Salary will be in the range of £8,574-£10,994 for Scientific Officer appointments and £10,026-£13,460 for Higher Scientific Officer appointments. Starting salary depends on experience and qualifications. Staff of the Council are not Civil Servants but their pay and conditions are similar to those on the Civil Service. There is a non-contributory pension scheme.

Application forms are available from the **Administration Officer, Institute of Virology and Environmental Microbiology, Mansfield Road, Oxford, OX1 3SR. Telephone: Oxford (0865) 512361.** Informal enquiries may be made to Dr Mark J Bailey, at the above address, for further details of the posts available.

### FACULTY POSITION IN MARINE REMOTE SENSING

The Applied Ocean Science Program at the University of Delaware's College of Marine Studies invites applications for tenure track faculty position to start anytime after September 1, 1989.

Requires Ph.D in the physical sciences or engineering, with strong background in theoretical and experimental work on hydrologic optics and/or ocean/coastal remote sensing desirable. Involves teaching at the graduate level, and development of an independent, funded research program on the optical and physical properties of particles and dissolved substances in estuaries and electromagnetic wave interaction with surface films, waves and particles. Opportunity to interact with ongoing research in remote sensing of wetlands and estuarine productivity; coastal circulation and fronts; air-sea interaction; spectral/spatial analysis of satellite imagery; electromagnetic and sound wave interaction with suspended particles; and Laser Doppler characterization of marine plankton.

Send resume with names and addresses of three references to: **Dr. Stephen C. Dexter, College of Marine Studies, University of Delaware, Lewes, DE 19958.** Closing date: July 1, 1989. *The University of Delaware is an Affirmative Action/Equal Opportunity Employer.* (NW3558)A

### MEDICAL RESEARCH COUNCIL LABORATORY OF MOLECULAR BIOLOGY, CAMBRIDGE

## Research in Organic Chemistry

Applications are invited for **post-doctoral** and **graduate positions** on the staff of the laboratory to join a research group working in the peptide and oligonucleotide field.

A PhD, first degree, or equivalent qualification in chemistry or a related subject is required. For both positions, experience in peptide synthesis or general organic synthesis and an interest in computer-controlled instrumentation would be an advantage. The post-doctoral position (ref D/5819) is initially of three years duration, subject to confirmation after the first year; salary within the range £11,070-£14,500 per annum (under review). The graduate appointment (ref D/2272) will be made on the Senior Technician scale which rises to a maximum of £12,347 per annum, with tenure after a six months probationary period. MRC Pension Scheme option, staff restaurant, and sports facilities.

Both positions are available immediately. Applications, including a curriculum vitae and the names of two professional referees should be sent quoting the appropriate reference by 30 April 1989 to:—

**The Personnel Officer  
MRC Centre  
Hills Road  
Cambridge  
CB2 2QH**

## DEPARTMENT OF BIOCHEMISTRY UNIVERSITY OF OXFORD

### Postdoctoral positions

#### Postdoctoral Research assistant 1a BR/287

#### CRC Growth Factors Research Group Growth and differentiation factors

Applications are invited for a postdoctoral 1a position in the CRC Growth Factors Research group. The successful applicant will be involved in the molecular cloning and structural characterisation of genes encoding novel polypeptide growth and differentiation factors active in early mammalian development. Techniques employed include DNA library construction, DNA sequencing, polymerase chain reaction and eukaryotic expression systems. Appropriate experience in these areas would be advantageous. The post is supported until December 1993 in the first instance. Salary scale: £9,865–£15,720 depending upon age and experience.

#### Postdoctoral Research Assistant 1a BR/288

#### Mammalian transgenesis

Applications are invited for a postdoctoral 1a position, supported by the AFRC Transgenic Animals Programme, for the exploitation of yeast gene control systems in transgenic animals. A background in yeast or mammalian gene expression and interest in acquiring experience in transgenesis techniques would be advantageous. The post is supported for three years from the date of appointment. Salary scale: £9,865–£15,720 depending upon age and experience.

Informal inquiries regarding both positions may be directed to Dr. John K Heath (tel. 0865/275721)

#### Postdoctoral Research Assistant 1a BR/289

#### Yeast/mammalian molecular genetics

Applications are invited for a postdoctoral 1a position, supported by the Wellcome Trust, for the molecular analysis of genes encoding sequence specific DNA binding proteins involved in centromere function in yeast, and their mammalian homologues. A background in yeast or mammalian molecular genetics would be an advantage. The post is supported for three years from October 1989. Salary scale: £9,865–£15,720 depending upon age and experience.

Informal inquiries may be directed to Dr. Jane Mellor (tel. 0865/275236)

Applications, quoting job number, a full c.v. and the names and addresses of two referees to: The Administrator

AN EQUAL OPPORTUNITY EMPLOYER

(8932)A

DEPT OF BIOCHEMISTRY, SOUTH PARKS ROAD, OXFORD, OX1 3QU.

## UNIVERSITY OF ST ANDREWS

### Department of Biochemistry and Microbiology POSTDOCTORAL RESEARCH ASSISTANT, GRADUATE RESEARCH ASSISTANT AND Ph.D STUDENTSHIP AIDS VACCINE DEVELOPMENT

Applications are invited for the above posts, funded by the MRC AIDS Directed Programme for three years, to develop and test the ability of novel immunogens to induce immunity to human immunodeficiency virus (HIV). The project will involve the construction of human adenovirus recombinants expressing HIV and SIV proteins, incorporation of the purified proteins into Solid Matrix-Antibody-Antigen Complexes and assessment of their ability to evoke humoral and cell-mediated immune responses. Successful candidates will join an active, well funded research group with excellent facilities for molecular virology.

For the postdoctoral and graduate research assistant positions experience in immunology (particularly T cell responses), virology or molecular biology would be particularly advantageous. Appointments can commence on 1st June 1989 or at a mutually agreed later date and will be on Research Assistant 1A scale £9,865 to £11,680 per annum, or 1B scale £8,675 to £10,460 per annum. The Ph.D studentship is to commence on 1st October 1989 and priority will be given to high quality candidates rather than background degree.

Further information can be obtained by telephoning Dr R E Randall or Dr R T Hay (0334 76161). Applications (two copies preferably in typescript) with the names of two referees should be sent to the **Director of Personnel Services, The University, College Gate, St Andrews, Fife KY16 9AJ** to arrive by 30th April 1989. (8923)A

## University of Minnesota Department of Pharmacology

### POSTDOCTORAL AND RESEARCH ASSOCIATE POSITIONS

The Department of Pharmacology, University of Minnesota Medical School, has Postdoctoral and Research Associate positions available in several fields. Our faculty members are well-funded and direct strong interdisciplinary research programs.

Positions are open to applicants upon receipt of a Ph.D. degree.

Areas of emphasis include:

**Molecular biology**, biochemistry, immunology, and neurobiology-neurochemistry

**Molecular cloning**, opioid receptor, receptor, and chemical biochemistry

**Intracellular electrophysiology**, ion channels

**Drug abuse**, neuropharmacology

**Biochemical/molecular pharmacology**

**Cancer chemotherapy**, immunopharmacology, drug metabolism, enzymology, and anti-viral drugs

Interested applicants should send a curriculum vitae, statement of research interests, and the names of three references to:

**Dr. Horace H. Loh, Professor and Head,  
Department of Pharmacology,  
3-249 Millard Hall,  
435 Delaware Street SE,  
Minneapolis, MN 55455.**

*The University of Minnesota is an equal opportunity educator and employer, and specifically invites and encourages applications from women and minorities.* (NW3555)A

## MEDICAL RESEARCH COUNCIL

### POST-DOCTORAL MOLECULAR GENETICIST

Applications are invited from suitably qualified applicants for a non-clinical scientist to join the Development Genetics Group on an established project studying the molecular basis of mutations affecting melanocyte development in the mouse. The work will involve DNA cloning, sequencing and manipulation, cell biology and mouse genetics, and experience in one or all of these areas will be an advantage. The position is available immediately for up to 3 years on a scale of £9260–£14500 (increase pending).

Enquiries should be made to Dr Ian Jackson, and applications containing the names and addresses of two referees should be sent to **The Unit Administrator, MRC Human Genetics Unit, Western General Hospital, Crewe Road, Edinburgh, EH4 2XU**, Telephone No 031-332 2471.

*The MRC is an equal opportunities employer.*

(8909)A

## University of Cambridge

### Department of Biochemistry

### PLANT BIOCHEMISTRY AND MOLECULAR BIOLOGY

Applications are invited for a postdoctoral research assistantship for work on the biochemistry and molecular biology of Photosystem I polypeptides involved in the ferredoxin-plastoquinone reductase system of cyclic phosphorylation in chloroplasts. The post is funded by AFRC and is available now for a period of up to 3 years, with a salary in the range £9,865–£12,760 according to age and experience.

Applications (with curriculum vitae and names of two referees) should be sent to **Dr. D.S. Bendall, Department of Biochemistry, Tennis Court Road, Cambridge, CB2 1QW**, as soon as possible. Further details from Dr. Bendall, Tel: 0223-333631/333630. (8899)A

# Infection Research

## Two Senior Appointments c £24,000 + car + benefits : Cheshire

As part of a major commitment to research in infection ICI wishes to appoint TWO SENIOR RESEARCH SCIENTISTS to work on exciting and challenging projects in multidisciplinary Project Teams within our Infection Research Programme. One position is for an experienced microbial biochemist to initiate research exploring new therapeutic targets for infection control in bacterial pathogens. The other is for an equally experienced scientist to investigate host defences and/or pathogenesis in an exploratory project aimed at the discovery of new approaches to the therapy of infections.

Candidates will have several years postdoctoral research experience in relevant aspects of microbial biochemistry or host immunity and the biology of infection processes. A knowledge of microbial genetics, in addition to microbial physiological

processes, will be an advantage for applicants for the biochemical post. An interest in chemotherapy of infection is essential.

Applicants should have had significant experience of supervising other research workers – juniors, graduates, PhDs – and must be able to provide evidence of working successfully in a team.

At ICI you will have the opportunity to fulfil your potential, utilise your scientific talent and progress your career in a rapidly expanding international business. An excellent benefits package includes pension, profit share, private healthcare and relocation assistance to this attractive part of the country.

**Please write with full c.v. and salary details, quoting reference AMS to: The Personnel Department, ICI Pharmaceuticals, Mereside, Alderley Park, Nr Macclesfield, Cheshire SK10 4TG.**

**Pharmaceuticals**

(8918)A

## Karolinska Institute Department of Molecular Biology POSTDOCTORAL POSITION

### Molecular Biology of Membrane Protein Assembly

We have an immediate opening for a postdoc interested in working on problems related to protein sorting and membrane protein assembly (see PNAS **85**, 3363-3366 and BBA **947**, 307-333). Our department is wholly focussed on this field, using current methods of molecular and cell biology such as site-specific mutagenesis and *in vitro* transcription-translation assays. Applicants should therefore have a good background in molecular-biology or microbiology.

Salary is 5500 Skr per month tax free (approx £500); in addition, apartment rent, health insurance, and travel costs are covered. The Department of Molecular Biology is a part of the Karolinska Institute and is located alongside the Karolinska Center for Biotechnology in Huddinge, south of Stockholm.

Please address all enquiries to: **Dr. Gunnar von Heijne, Department of Molecular Biology, Karolinska Institutet, Huddinge Hospital-K87, S-141 86 Huddinge, Sweden. Phone: Int +46-8-774 7699 (W6028)A**

## UNIVERSITY OF COLORADO, SCHOOL OF MEDICINE, DENVER, COLORADO DEPARTMENT OF PHARMACOLOGY CHAIRPERSON

Applications and nominations are invited from candidates for the Chairperson of the Department of Pharmacology. Individuals with a strong commitment to medical and graduate education and distinguished accomplishments in basic research are encouraged to apply.

Please send curriculum vitae and names of references to:

Dr. Frederick C. Battaglia  
Chairperson, Pharmacology Search Committee  
Department of Pediatrics, School of Medicine  
University of Colorado Health Sciences Center  
4200 E. 9th Avenue, Denver, CO 80262

An equal opportunity/affirmative action employer. N(W3568)A

Biology

## Drug Delivery

Smith Kline and French Laboratories, a leader in pharmaceutical research, is currently building a strong multidisciplinary drug delivery department of approximately 30 scientists. This group, located in suburban Philadelphia, will be investigating membrane and transport processes that can be utilized for the delivery of conventional and biotech drugs, and the design of therapeutic systems to meet the biological needs of specific drugs and diseases.

We are therefore seeking outstanding individuals to work in the following areas:

- Drug Absorption
- Drug Targeting
- Drug Carriers

Ph.D. and non-Ph.D. scientists with backgrounds in either cell biology, physiology, biochemistry, biophysics, or chemistry, and a desire to be part of a highly interactive team, are invited to apply. Previous experience of drug delivery research and development is not a prerequisite.

Based in a new, state-of-the-art research facility near Valley Forge, Smith Kline and French provides a stimulating and challenging environment in which to grow and excel. We offer an attractive compensation/benefits and relocation package. For confidential review forward your C.V. and the names of three references to: Terry Gallagher, T103, Smith Kline & French Laboratories, Research and Development, P.O. Box 1539, King of Prussia, PA 19406-0939. We are an Equal Opportunity Employer, M/F/H/V.

UNIVERSITY OF LONDON

## **Research Co-ordinator Science Planning Unit**

**Salary circa  
£15,000 per annum**

This large Postgraduate Medical School which includes the Institutes of Cancer Research, Child Health, Dental Surgery, Neurology, Ophthalmology and Psychiatry, and the National Heart and Lung and Hunterian Institutes, is establishing a new science Planning Unit to assist in the development and implementation of an academic plan.

The Research Co-ordinator, a graduate preferably with experience in data handling/computing, will be responsible for the day to day running of the project, maintaining close links with Institute staff and the Regional Deans in Medicine and Dentistry.

Further information and application forms are available from Jane M. Jones, Federation Secretary, BPMF, 33 Millman Street, London WC1N 3EJ (Telephone 01-831 6222) to whom applications should be forwarded by 20 April 1989. (8847)A

## **SYSTEMS NEUROSCIENCE, CELLULAR NEUROSCIENCE, MOLECULAR NEUROSCIENCE; FACULTY POSITIONS DEPARTMENT OF NEUROBIOLOGY AND BEHAVIOR —SUNY STONY BROOK:**

The Department of Neurobiology and Behavior of SUNY Stony Brook is continuing its search for candidates for tenure-track, state-funded positions beginning as early as academic year 1989/90. The Department, which currently consists of 15 members, is undergoing significant redevelopment, and has the resources to grow to 20 members within the next 5 years. Presently available positions are at the Assistant Professor level although an appointment at the rank of associate Professor could be considered. Rank and competitive salaries will be commensurate with qualifications. All applicants should have a minimum of 2 years of postdoctoral experience. Candidates will be expected to develop a vigorous independent research program, and as such ample space and start-up funds will be provided.

Applicants should submit a curriculum vitae, statement of research interests, and names and addresses of three references to: **Dr. Lorne Mendell, Chairman, Department of Neurobiology and Behavior, SUNY Stony Brook, Stony Brook, NY 11794-5230.** SUNY Stony Brook is an affirmative action/equal opportunity educator and employer. AK 60. (NW3516)A

## **AFRC INSTITUTE FOR ANIMAL HEALTH**

Compton, Newbury, Berkshire. RG16 0NN

## **A Head of Division is required for Immunology and Pathology**

Following a major restructuring of the Institute two major divisions: Molecular Biology, and Immunology and Pathology, and two smaller divisions: Environmental Science, and Epidemiology, have been formed. We are seeking to appoint a Head of Division of Immunology and Pathology.

The post will be located at Compton but the successful applicant will be expected to manage an integrated programme across the two major sites at Compton and Pirbright and the Neuropathogenesis Unit in Edinburgh. Opportunities exist to work on a number of endemic and exotic diseases of farm animals and develop fundamental and applied programmes. The Head of Division will plan financial provision, control budgets, encourage collaborative links both within the UK and overseas and take an active role in the management of the Institute.

The successful candidate will have the opportunity to introduce and develop new research topics and appoint to a number of new posts. He/she will be responsible to the Director of Research, Professor F. J. Bourne.

Applicants will have a higher degree and broad experience in modern immunological techniques, distinction in a relevant area of immunological research and an ability to manage scientific personnel.

The appointment will be at Unified Grade 5 with a salary on the scale £28,170-£31,602 with opportunity for further, performance-related increments to £36,786. There is a non-contributory superannuation scheme.

Application form and further details are available from the **Personnel Officer, AFRC Institute for Animal Health, Compton, Berks, RG16 0NN.**

Closing date: 23 April 1989.

(8861)A

## **ANIMAL BIOTECHNOLOGY CAMBRIDGE LTD**

### **SENIOR MOLECULAR BIOLOGIST**

ABC Ltd is a rapidly expanding company in the forefront of the development of advanced transgenesis for the Pharmaceutical, Food and Livestock Industries. We have extensive in-house expertise in animal embryology, *in vitro* culture, stem cell technology and micro-manipulation.

We are looking for an accomplished Molecular Biologist with commercial awareness, to take responsibility for all molecular aspects of our programme and to participate in the development of contracts with our clients.

The successful candidate will have experience in recombinant DNA technology, mammalian gene cloning, and tissue culture. He or she will be responsible for preparing research proposals, setting up projects and managing them. In return we offer a competitive salary and fringe benefits, and the opportunity to work with a well-funded and dedicated team in a stimulating R&D environment.

*Please send your application, including CV and detailed description of previous relevant experience to:*

**Dr Martin Evans**

**Director of Transgenesis**

**Animal Biotechnology Cambridge Ltd**

**Animal Research Station**

**307 Huntingdon Road, Cambridge CB3 0JQ**

**Telephone: (0223) 277222 (8860)A**

Postdoctoral positions are now available at the Center for Advanced Biotechnology and Medicine, a newly established molecular biology research program jointly administered by Rutgers University and the University of Medicine and Dentistry of New Jersey

and funded by the N.J. Commission on Science and Technology. Competitive stipends and benefits are provided.

**Structural Biology:** Three positions examining the molecular basis of cancer. NMR Spectroscopist: to develop 2D- and 3D-heteronuclear experiments to characterize the structure and dynamics of proteins in solution. Theoretical Protein Chemist: to implement and develop methods for determining protein structures from NMR data using distance geometry and conformational energy calculations and to aid in molecular modeling and design of transforming growth factors. Experimental Protein Chemist: to perform NMR structural studies, isotope enrichment, and purification of transforming growth factors and mutant analogs. Send CV, summary of research interests, and names of three references to Dr. Gaetano Montelione.

**Molecular Genetics:** Two positions in experimental protein design. Mutagenesis approaches will be used to study problems in molecular recognition, especially ligand:receptor and enzyme:substrate interactions. Applicants should have a strong grounding in chemistry, biochemistry, or biophysics and a desire to apply the techniques of molecular genetics to problems in structural biology. Send CV, a short summary of research interests, and names of three references to Dr. Stephen Anderson.

CABM, 675 Hoes Lane, Piscataway, NJ 08854-5635.

An Affirmative Action-Equal Opportunity Employer.

(NW3552)A

## INSTITUTE OF VIROLOGY AND ENVIRONMENTAL MICROBIOLOGY (OXFORD)

### RESEARCH VACANCIES MOLECULAR BIOLOGY AND ECOLOGY

Applications are invited for research positions in both molecular biology and ecology.

The subject areas are as follows:

#### At post-doctoral, (HSO) level

- 1 Development of novel recombinant retroviral vaccines.
- 2 Release of genetically marked bacteria into the environment, genetic and ecological considerations.

#### At post-graduate, (SO) level

- 1 Environmental investigations into the fate and persistence of phyloplane bacteria.
- 2 Ecology of insect viruses and their use as pest control agents.
- 3 Molecular biology of RNA virus replication.

Applicants should preferably have experience in molecular biology and/or ecology.

Salary will be in the range of £8,574-£10,994 for Scientific Officer appointments and £10,026-£13,460 for Higher Scientific Officer appointments. Starting salary depends on experience and qualifications. Staff of the Council are not Civil Servants but their pay and conditions are similar to those of the Civil Service. There is a non-contributory pension scheme.

Application forms are available from the **Administration Officer, Institute of Virology and Environmental Microbiology, Mansfield Road, Oxford, OX1 3SR.** Telephone: Oxford (0865) 512361.

The Natural Environment Research Council is an equal opportunity employer

(8921)A

## AFRC INSTITUTE OF ANIMAL PHYSIOLOGY AND GENETICS RESEARCH EDINBURGH RESEARCH STATION POSTDOCTORAL RESEARCH IN TRANSGENIC ANIMALS

The Research Station is a leading centre in transgenic biology (see Nature, 328, 530-532; 331, 70-72; Bio-technology 6, 179-183). We have embarked on a major expansion in this area and are applying gene transfer techniques in both laboratory and farm animals to critical problems of gene regulation, physiology and development. Within this programme the following postdoctoral research positions are still available.

1. Control of Milk Protein Gene Expression. The research will define the DNA sequences and their interaction with specific transcription factors that underly tissue-specific expression in the mammary gland. The work will be carried out *in vitro* and in transgenic mice. The person appointed will have experience in recombinant DNA techniques. Contact John Clark, 031-667-6901.
2. Manipulation of Milk Composition. The project will involve introducing genes encoding caseins and genetically engineered derivatives into transgenic animals and assessing the effects of their expression on milk composition and properties. The work will be carried out in collaboration with the Hannah Research Institute, Ayr. The person appointed will have experience in recombinant DNA techniques. Contact John Clark, 031-667-6901.
3. Germline transformation of poultry. A molecular biologist is required to join a project to develop a method to produce transgenic poultry by injection of DNA at the single cell stage, followed by *in vitro* embryo culture. The project will involve developing methods to detect the integration of injected sequences and an investigation of the possible use of episomal vectors. For further information contact Helen Sang, 031-440-2726.
4. Increased efficiency of gene transfer in sheep. The objective is to use the polymerase chain reaction to study the integration of DNA sequences in the early embryo after micro-injection. Methods will be developed for 1), selecting transgenic embryos before transfer to recipients and 2), investigating factors that influence the frequency of integration. Experience of working with mammalian embryos would be an advantage. Contact Ian Wilmut, 031-440-2726.

The Research Station occupies new laboratories within and just outside Edinburgh and carries out basic research in animal genetics, molecular biology and physiology; it has close links with biology departments within Edinburgh University and, in addition, will retain facilities within the newly formed interdisciplinary Research Centre.

Condition: All posts are tenable for three years in the first instance. They are all at the HSO grade, except post 3 which may be offered at the SSO grade. Salary in HSO scale £10,026-£13,460 (HSO), 22 days annual leave; £12,445-£17,032 (SSO), 22 days annual leave.

Application forms (specify which posts) can be obtained from **Mrs. L. Hunter, Personnel Officer, AFRC Institute of Animal Physiology and Genetics Research, Edinburgh Research Station, Roslin, Midlothian EH25 9PS**, and should be completed by 30th April, 1989. (8926)A

## COMMISSARIAT A L'ENERGIE ATOMIQUE INSERM Département de Biologie U150 EICOSANOÏD RESEARCH

A post-doctoral position is available in a joint project between CEA (Commissariat à l'Energie Atomique) and INSERM (Institut National de la Santé et de la Recherche Médicale) for an individual interested in learning and developing techniques of immunoanalysis for eicosanoids metabolites and their enzymes of biosynthesis (the project will involve enzyme purification, obtention of monoclonal antibodies, preparation of enzymatic tracers). The study will be focused on the development of immunocytochemistry using these reagents. Application of these techniques to blood and vascular cells will also be performed.

The candidate should also have been involved in one of these topics: Analytical Biochemistry, Biochemistry, Pharmacology, Immunochemistry. Send or fax (1) 69 08 73 00 letter of interest, CV and the names of three referees to:

**Dr P. PRADELLES**

## The Center for Advanced Research in Biotechnology (CARB)

### MOLECULAR MODELING OF ANTIBODY-ANTIGEN INTERACTIONS

IGEN Inc. wishes to appoint a post-doctoral CARB-IGEN fellow to work on the development of computer algorithms for determining the mode of interaction of antigens with antibody molecules. The successful applicant will be based primarily at the new CARB facility at the Shady Grove Campus of the University of Maryland in Rockville, Maryland, outside Washington, DC. He or she will also interact closely with the IGEN team developing catalytic antibody technology. In addition, collaboration with the antibody engineering group of Dr. A.R. Rees at the University of Oxford will be possible.

The successful candidate will have experience in the development of software for the computer modeling of protein structure and function, and will have a keen interest in meeting the challenges posed by the antibody antigen recognition problem.

Please send a current CV, and a list of 3 individuals who will serve as references to: **Dr. John Moulton, CARB, 9600 Gudelsky Drive, Rockville, MD 20850.** The University of Maryland is an equal opportunity employer.

*CARB is a joint venture between the University of Maryland and the National Institute of Standards and Technology. CARB's goal is to build a center of research excellence in the area of protein structure, function, engineering and design. Molecular modeling is an important component of this program, and is supported by a number of Silicon Graphics workstations and an Alliant minisuper-computer.*

### CATALYTIC ANTIBODIES

IGEN Inc. is seeking a post-doctoral scientist with experience in computational chemistry of small molecules to join its team on the design of transition state analogues for use in the production of catalytic antibodies. Knowledge of protein structure and function would also be an advantage. The successful candidate should be able to participate in the academic activities of CARB.

Please send a current CV, and a list of 3 individuals who will serve as references to: **IGEN Inc., Human Resource Manager, 1530 East Jefferson Street, Rockville, Maryland 20852.**

*IGEN is a biotechnology company located in Maryland close to Washington, DC, specializing in the development of a new generic diagnostic technology and in the pharmaceutical and therapeutic applications of catalytic antibodies (ABZYMES™).*

Faculty of Natural Sciences

## FACULTY POSITION IN BIOCHEMISTRY

Applications are invited for a tenured faculty position (associate professorship, Extraordinariat) at the Department of Biochemistry. Candidates are expected to have a creative research programme in protein biochemistry and a genuine interest in the teaching of biochemistry to medical and science students.

Applications including curriculum vitae, bibliography synopsis of past and planned future research, and a record of teaching experience should be sent to the Chairman of the Search Committee, Professor Christian Bauer Physiologisches Institut der Universität Zürich, Winterthurerstr. 190, CH-8057 Zürich, Switzerland.

Deadline June 15, 1989.

(W6022)A

## CHAIR DEPARTMENT OF VETERINARY BIOLOGY College of Veterinary Medicine University of Minnesota

Applications and nominations are invited for a tenured Professor and Chair of the Department of Veterinary Biology. The department includes 17 faculty in the disciplines of anatomy, biochemistry, physiology and pharmacology, and occupies modern laboratory and teaching facilities. The College is located on the Twin Cities Campus in St. Paul with the opportunity for interaction with colleagues from many other units of the University including the Medical School, the College of Biological Sciences and the College of Agriculture. Our location also provides the cultural advantages of a large metropolitan area together with proximity to a wide variety of outdoor activities.

Candidates must have the Ph.D. degree or relevant foreign equivalent and preference will be given to individuals who also hold the D.V.M. degree or foreign equivalent. The appointee will be expected to have a distinguished record of research and teaching accomplishments, with proven leadership and administrative abilities. The appointee must be able to: 1) provide leadership, both in professional and graduate education, and in developing competitive research programs, and 2) have an understanding of future trends in the veterinary profession and current issues relating to veterinary medical education. Letters of application should include a current curriculum vitae and a statement of goals, plus names and addresses of at least 3 persons who will provide letters of reference.

Applications with supporting material will be accepted until June 15, 1989, and should be sent to **Dr. Alice A. Larson, College of Veterinary Medicine, University of Minnesota, St. Paul, Minnesota 55108.**

*The University of Minnesota is an equal opportunity educator and employer and specifically invites and encourages applications from women and minorities.*

(NW3547)A

## Post Doctoral Research at The Wistar Institute

Post doctoral positions are available at The Wistar Institute for candidates with a strong background in molecular and cell biology, virology, immunology, genetics or protein chemistry. Specific areas of research include: human retroviruses; DNA/RNA tumor viruses; growth factors; oncogenes; pattern formation in embryos; molecular mechanisms involved in the immune response; x-ray crystallography of virus receptor interaction; and aging in tissue culture. The Wistar Institute is an independent institution, located on the campus of the University of Pennsylvania and is equipped with the latest biotechnology facilities.

Starting salary at \$20,000 a year. Interested applicants are requested to send a curriculum vitae and the names of 3 references to: **Coordinator of Research Training, THE WISTAR INSTITUTE, 36th and Spruce Streets, Philadelphia, PA 19104.** Equal opportunity employer, M/F.

## DEPARTMENT OF PSYCHIATRY UNIVERSITY OF TORONTO

### Applications are invited for the position of ASSISTANT PROFESSOR

in the area of Molecular Neurogenetics as applied to psychiatric disorders. This position requires a Ph.D. or other doctoral degree and significant post-doctoral experience in molecular genetics, molecular neurobiology or an equivalent field. The successful candidate will be expected to work collaboratively with a multidisciplinary neuroscience/neuropsychiatric research group comprised of basic and clinical researchers investigating the neurobiology and neurogenetics of psychiatric disorders. The position requires demonstrated ability to conduct independent research within a collaborative group and to compete for extramural funding.

The position is tenure track equivalent supported initially by the I'Anson fund. Salary is commensurate with rank and experience. The position also includes a one time start up research grant.

The University encourages both men and women to apply for positions. In accordance with Canadian immigration requirements, this advertisement is directed to Canadian citizens and permanent residents of Canada.

Candidates should submit a letter of application, a curriculum vitae and the names of three referees from whom letters of recommendation may be solicited. Please submit responses to: **Dr. Jerry I. Warsh, Director of Research, Clarke Institute of Psychiatry, 250 College Street, Toronto, Ontario M5T 1R8.**

The successful candidate would be expected to take up the appointment prior to September 1, 1989.

**Closing date for applications is May 19, 1989.** (NW3559)A

## NATIONAL UNIVERSITY OF SINGAPORE INSTITUTE OF MOLECULAR AND CELL BIOLOGY

### POST-DOCTORAL APPOINTMENT IN HYBRIDOMA TECHNOLOGY

The Institute of Molecular and Cell Biology invites applications from candidates who have expertise in hybridoma technology.

The Institute, which was recently established to undertake basic biomedical and biotechnological research, has three principal research areas related to Cell Regulation, Infectious and Genetic Diseases and Molecular and Cell Biology of Plants. The Institute, which is adjacent to the University's biomedical complex and the National University Hospital, has 19 laboratory modules of 500 square feet each.

The successful candidate should have post-doctoral experience in the field of hybridoma technology. He/She will be required to provide a service for generating monoclonal antibodies and also undertake an independent research programme.

Salary will be commensurate with experience; leave, medical and other benefits will be provided. Applicants should send their curriculum vitae and names and addresses of 3 referees to the:

**Director  
Personnel Department  
National University of Singapore  
10 Kent Ridge Crescent  
Singapore 0511**

Enquiries may also be sent through BITNET to:

## SCIENTIST- CYTOGENETICIST

### Animal Gene Mapping Programme Biotechnology Division

The DSIR is the largest scientific research organisation in New Zealand. Three Divisions (Grasslands, Biotechnology and Plant Physiology) are based in the Palmerston North Centre.

Palmerston North (population 70,000), is located in a pleasant rural area, about three quarters of an hour's drive from the coast. The city caters for a wide range of recreational activities and has excellent educational facilities.

The Animal Gene Mapping programme is an expanding group involved in mapping the genomes of sheep, cattle and horses in the Animal Gene Technology programme.

A permanent position exists for a Cytogeneticist with experience in high resolution banding, in-situ hybridisation, and comparative karyotyping of mammalian chromosomes.

The person will be actively involved in collaborating with molecular geneticists in constructing a physical map of the sheep genome.

Applicants should possess a Ph.D in genetics, biochemistry, physiology or zoology and have suitable post-graduate experience in human, or preferably, animal cytogenetics.

The ability to work effectively in a multi-disciplinary group situation is essential.

Salaries will be commensurate with qualifications and experience. Relocation expenses are negotiable. Promotion and career advancement are dependent on performance.

Please apply in writing quoting reference No. BIO 18, enclosing a curriculum vitae and the names of at least two referees by April 27, to:

The Personnel Officer,  
DSIR, Private Bag  
Palmerston North

Fax: (063) 61-130, Phone: (063) 68-019

An equal opportunity employer.

## THE AUSTRALIAN NATIONAL UNIVERSITY

POSTDOCTORAL FELLOW/  
RESEARCH FELLOW, DIVISION OF  
CLINICAL SCIENCES

The John Curtin School of  
Medical Research

The colon cancer group seeks an experienced molecular biologist to join its study of colon epithelial transformation, invasion and metastasis. The successful applicant will contribute to an established project researching the genetic basis of colon cancer at a molecular level, including the defective alleles identified in hereditary and sporadic forms of colon cancers. The laboratories are fully equipped for molecular biology.

Enquiries may be directed to: Dr N.G. Ardlie, Acting Head of the Division of Clinical Sciences (062) 492885, The John Curtin School of Medical Research. Closing date: 5 May 1989. Ref: JC17.3.1.

Salary: Research Fellow; A\$30,737-A\$40,100 p.a. Postdoctoral Fellow Grade 1 (fixed point): A\$26,617-A\$30,360 p.a. Appointment: Research Fellow up to three years, possibility of extension to five years; Postdoctoral Fellow normally two years, possibility of extension to three years. Applications should be submitted in duplicate to the Registrar, The Australian National University, GPO Box 4, Canberra ACT 2601, Australia, quoting reference number and including curriculum vitae, list of publications and names of at least three referees. The University reserves the right not to make an appointment or to appoint by invitation at any time. Further information may be obtained from the Registrar or from Appointments (36191), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.

The University is an Equal Opportunity Employer (W6025)A

### UNIVERSITY OF DUNDEE DEPARTMENT OF BIOLOGICAL SCIENCES RESEARCH ASSISTANTS IN PLANT MOLECULAR BIOLOGY

Applications are invited for the position of Postdoctoral Research Assistant (1A) and Postgraduate Research Assistant (1B) to join a group studying the splicing of pre-mRNAs in plants. The programme is AFRC-funded for 3 years and will involve the isolation of plant UsnRNA genes and the study of their genetic organisation and expression.

The postdoctoral RA will be appointed on the 1A scale (starting salary (£9,865-£11,070) and the postgraduate RA on the 1B scale (£8,675).

Further information is available from Dr John W S Brown, Tel. 0382-23181 Ext. 4278.

Applications (CV and names of 2 referees) to the Personnel Office, The University, Dundee, DD1 4HN, quoting Ref: EST/412/89/N. Closing Date: 30 April 1989.

(8891)A

## OXFORD UNIVERSITY NUFFIELD DEPARTMENT OF PATHOLOGY

### Project on the Spread of Cancer in the Human Body Research Assistant Grade 1A

Applications are invited from postdoctoral scientists for a responsible position in a team studying basic cellular and molecular mechanisms by which malignant tumours spread (metastasis) to distant organs in the body. The challenge of the job is that it focuses directly on the major problem of cancer: namely the formation of multiple scattered secondary tumours and how to control their growth. Experience in cell biology, biochemistry/molecular biology/virology or genetics will be an advantage but not essential, if the candidate has other relevant practical expertise.

Starting salary up to a maximum of £14,500 on the University Research Staff 1A scale (£9,815,720), depending on age and experience. The project is financed for 3 years by the Cancer Research Campaign and the post is vacant.

Further information may be obtained from: Dr. D. Tarin, Nuffield Reader in Pathology, Nuffield Department of Pathology, John Radcliffe Hospital, Headington, Oxford OX3 9DU. (Telephone (Oxford) (0865) 817797) to whom applications with full c.v. and names of 2 referees should be submitted by 27/4/89.

Oxford University is an equal opportunity employer.

(8886)A

## POSTDOCTORAL POSITIONS

Three postdoctoral positions available immediately in the Laboratory of Viral Diseases, NIAID. Dr. Bernard Moss, Laboratory Chief. Studies include 1) Biosynthesis, assembly and transport of HIV proteins using monoclonal antibodies (Dr. Jonathan Yewdell, see Cell 52: 843, 1988) and 2) CD4 gp120 interactions and the design of CD4-based targeted AIDS therapeutics (Dr. Edward Berger, see Nature, 335: 369, 1988). Experience in hybridoma technology, protein chemistry, genetic engineering, or HIV virology preferred but not required. Starting salary commensurate with experience. Curriculum vitae and four letters of reference to:

Dr. Jonathan Yewdell  
NIAID, Twinbrook II  
12441 Parklawn Drive  
Rockville, MD 20852

or

Dr. Edward Berger  
NIAID, NIH  
Bldg. 4, Room 232  
9000 Rockville Pike  
Bethesda, MD 20892

NIH IS AN EQUAL OPPORTUNITY EMPLOYER

## CITRUS HORTICULTURIST

Academic career-track, 11-month Assistant or Associate Horticulturist in Integrated Citrus Management to develop more efficient cultural practices for citrus production, especially in the areas of nutrition and irrigation. The position is a 75% Agricultural Experiment Station research appointment with a 25% appointment in Cooperative Extension within the Department of Botany and Plant Sciences at the University of California, Riverside. Responsibilities include development of a research program to adapt and test the efficacy of major advances in basic research to the production of citrus. Field research will be conducted at appropriate off-campus locations, including the San Joaquin Valley.

Extension responsibilities include conducting training sessions and short courses to disseminate research results to the industry and to facilitate their implementation by growers. The position is intended to combine aspects of both applied and basic research. Requires a Ph.D. degree specializing in Plant Physiology, Botany, Horticulture, or other plant science with demonstrated experience in designing, conducting, analyzing, and interpreting field research, especially the physiology of plant nutrition or irrigation of tree crops.

Send letter of application, curriculum vitae, statement of research interest, transcripts (recent graduates), and at least three confidential letters of evaluation to: **Dr. Carol J. Lovatt, Chair, Search Committee, Department of Botany and Plant Sciences, University of California, Riverside, CA 92521.** The application deadline is May 31, 1989.

*The University of California, Riverside, is an Affirmative Action/Equal Opportunity Employer. Minorities and women are encouraged to apply.* (NW3546)A

### UNIVERSITY OF CAMBRIDGE

#### Department of Biochemistry

#### POSTGRADUATE AND POSTDOCTORAL RESEARCH ON SUGAR TRANSPORT PROTEINS

Certain bacterial sugar transport proteins are homologous to the mammalian glucose transporters (*Nature*. 325, 641, 1987; *J. Biol. Chem.* 263, 8003, 1988; *Ann. Rev. Physiol.* 51, 459-471, 1989). Their molecular architecture and mechanism are being elucidated by a combination of protein chemistry, mutagenesis, recombinant DNA techniques, gene sequencing, etc. Facilities for automated nucleotide synthesis, peptide synthesis and protein sequencing are available.

Applicants for a postdoctoral research post (age-related scales £12,415 - £14,500) or Ph.D. studentships may be a qualified in Biochemistry, Genetics, Microbiology or allied subjects. Send full C.V. plus names of two referees to **Dr Peter Henderson, Department of Biochemistry, University of Cambridge, Tennis Court Road, Cambridge, CB2 1QW.** Tel: (0223) 333622. (8898)A

### JUNIOR FACULTY POSITION

available in the pharmacology and biochemistry of antineoplastic agents targeted against specific human cancer types. Studies will involve the modulation of anticancer agents with thymidylate synthase as the primary target. The focus will be on metabolism of reduced folates, modulation of reduced folate pools, and optimization of drug scheduling for therapeutic gain. Research will also identify factors that influence the regulation and turnover of thymidylate synthase in elucidating the importance of the enzyme as a therapeutic target. Candidates should have the Ph.D. degree with a minimum of 3 years postdoctoral experience. A strong background in Biochemistry is advantageous. Send curriculum vitae and names of 3 references to:

**Dr. J. A. Houghton,  
Laboratories for Developmental Therapeutics,  
Department of Pharmacology,  
St. Jude Children's Research Hospital,  
332 North Lauderdale, Memphis, TN 38101.**

*Equal Opportunity/Affirmative Action Employer.* (NW3556)A

*The Polytechnic operates a range of degree and post graduate level courses, has a vigorous and successful record of consultancy and research. Due to Corporate Status the Polytechnic has entered a new and challenging phase of its development. To maintain and extend the programme of work, applicants are invited for the following post:*

### FACULTY OF SCIENCE

## Head of School of Pharmaceutical and Chemical Sciences

£24,084 - £26,538

Applicants for the post should possess both high academic credibility and the ability to manage and lead the School as a budget centre.

The School of Pharmaceutical and Chemical Sciences is one of three Schools in the Faculty of Science and covers the disciplines of pharmacy (except for pharmacology) and of chemistry. The School has an establishment of over 30 academic staff.

The person appointed would be eligible for consideration for appointment to the Professoriate.

This is a readvertisement; applications from candidates responding to the previous advertisement for the post will be taken into consideration — there is no need for a re-application.

**Further details and application forms are available from Personnel Services, Langham Tower, Ryhope Road, Sunderland SR2 7EE, or telephone (091) 5152429. Informal enquiries may be made to Professor J. R. Brown, Dean of Faculty, telephone 091 5152504.**

**Closing date: 30th April, 1989.**

(8941)A

## SUNDERLAND POLYTECHNIC

### UNIVERSITY OF EDINBURGH

#### Department of Preclinical Veterinary Sciences

### LECTURESHIPS

Applications are invited for two Lectureships in the above Department which has teaching and research commitments in Anatomy, Biochemistry, Pharmacology and Physiology.

**Lectureship in Systems Physiology.** This post will be funded under the terms of the New Academic Appointments Scheme and will be available from October 1989 subject to UFC approval. The holder will be expected to pursue research in some branch of mammalian systems physiology and encouraged to seek external funding for research. Systems of particular interest to the Department are the cardiovascular and respiratory systems but applicants with research interests in other fields of mammalian physiology will also be considered. The successful applicant would be expected to participate in the undergraduate teaching and postgraduate training programmes of the Department. The initial salary will be on the Lecturer A scale (£9,260-£14,500 p.a.) or exceptionally on the Lecturer B scale (£15,105-£19,310 p.a.) Ref. No. 1425

**Lecturer in Biochemistry.** This post is tenable from October 1989 and arises from the retirement of a member of staff. It is a joint appointment held in the Departments of Preclinical Veterinary Sciences and Biochemistry. Candidates should be active in any aspect of biochemistry, cell biology or molecular biology relevant to veterinary science. The successful applicant would be expected to participate in undergraduate teaching and postgraduate training programmes of both departments and encouraged to seek external funding.

Salary will be on the Lecturer Scale A (currently £9,260-£14,500 p.a.) Ref. No. 1426 Applications (six copies) including a curriculum vitae and the names and addresses of two referees, should be submitted in writing to **The Secretary to the University, Old College, South Bridge, Edinburgh, EH8 9YL.** The closing date for applications is 1st May 1989. The appropriate reference number should be quoted in the application. Enquiries, which are welcomed, should be directed to Professor C. R. House, Department of Preclinical Veterinary Sciences, University of Edinburgh, Summerhall, Edinburgh, EH9 1QH (telephone number, 031-667-1011, Ext. 5344). (8910)A

**MRC PROTEIN PHOSPHORYLATION GROUP  
BIOCHEMISTRY DEPARTMENT, UNIVERSITY OF DUNDEE**

**POSTDOCTORAL  
POSITIONS**

Following expansion of the research programme by the Medical Research Council, several postdoctoral positions have become available to work with Professor Philip Cohen and Dr Tricia Cohen. The work is interdisciplinary and applications are invited from candidates with experience in any of the following areas; molecular genetics, protein chemistry, enzymology, molecular pharmacology and immunocytochemistry. A major aspect of the research is concerned with the structure and regulation of protein phosphatases. Recent work within the Group has demonstrated that these enzymes play key roles hormonal regulation in cell division and in tumour suppression, and several new phosphatase genes have been isolated. Novel mechanisms for controlling their activities have also been identified that involve interaction with specific targeting subunits. The positions are available from October 1989, but candidates wishing to start at any time up to Spring 1990 will be considered. The appointments are for three or five years in the first instance and will be made at an appropriate point on the University Grade 1A scale, depending on qualifications and experience.

The Department is one of the most highly funded in Britain and offers outstanding research facilities and working environment. Housing and accommodation costs are among the lowest in the UK and access to outdoor recreational facilities is unrivalled.

Applications containing a full curriculum vitae and the names and addresses of three referees should be sent to **Professor Philip Cohen, FRS, FRSE, Department of Biochemistry, The University, Dundee DD1 4HN, Tayside, Scotland** as soon as possible. Informal enquiries by telephone (0382-23181) to either Philip Cohen (ext 4238, 4241) or Tricia Cohen (ext 4240). (8901)A

**UNIVERSITY OF GLASGOW  
ORAL BIOLOGY GROUP  
POST-DOCTORAL (BIOCHEMISTRY)  
RESEARCH ASSISTANT**

Applications are invited from suitably qualified candidates for the post of Research Assistant for a Biochemistry (Range 1A) project in the Dental Hospital and School Oral Biology Group.

Applicants must have a good honours degree in Biochemistry or an allied subject and possess (or expect to possess shortly) a Ph.D. in this discipline.

The Group has well equipped laboratories and the work will involve the analysis of dietary carbohydrate in saliva and dental plaque by HPLC. The project is supported by a research contract with Mars Confectionery. The appointment will be for a period of one year with the possibility of renewal of contract for a further year.

Starting Salary — £9,865 (under review) including U.S.S.

Appointment to commence immediately.

Applications, together with a C.V. and the names of two academic referees should be sent to:

**Dr D.A.M. Geddes and Dr J.A. Beeley,  
Oral Biology Group,  
Glasgow Dental Hospital & School,  
378 Sauchiehall Street, Glasgow, G2 3JZ**

from whom further particulars may be obtained.

Closing date: 21st April, 1989.

(8904)A

**UNIVERSITY OF ABERDEEN  
DEPARTMENT OF BIO-MEDICAL PHYSICS AND BIO-ENGINEERING**

**RESEARCH FELLOW**

The successful applicant will work on a joint project with the Department of Ophthalmology on the potential of digital techniques in retinal imaging. The post-holder will work closely with ophthalmologists and will be responsible for developing software for image analysis and the assisting with the design of optical systems. Ability to program in C is essential and familiarity with optical design would be an advantage. The post is tenable for one year, within the range £9,865-£12,760 on the Research and Analogous Staff Scale 1A, depending upon qualifications and experience.

Informal enquiries to Dr P Sharp on 0224 681818 ext 53209. Further particulars and application forms from **The Personnel Office, The University, Regent Walk, Aberdeen AB9 1FX**, to whom applications (2 copies) should be returned by 28 April 1989 quoting reference number LW/014. (8913)A

**THE AUSTRALIAN  
NATIONAL UNIVERSITY  
POSTDOCTORAL FELLOW/  
RESEARCH FELLOW IN  
VISUAL  
ELECTROPHYSIOLOGY**

Centre for Information Science Research

Applications are invited from suitably qualified electrophysiologists with experience in intracellular electrophysiology, dye injection and computer-aided data collection and analysis, to work with a team in the Centre for Visual Sciences, investigating visual processing in insects. A PhD is essential, and experience in investigating processing at higher levels of the visual pathway is highly desirable. This post is funded by the Centre for Information Science Research and it is expected that the successful applicant will be involved in the Centre's activities.

For further information contact Dr M. W. Srinivasan (tel. [010-61] (062) 492409, Fax No. 489995, Telex No. [AA] 62219.)

Closing date: 30 April 1989 Ref: CIS 22.3.1

**SALARY:** Research Fellow: A\$30,737-A\$40,100 p.a.; Post-doctoral Fellow Grade 1 (fixed point); A\$26,617-A\$30,360 p.a. **APPOINTMENT:** Research Fellow up to three years, possibility of extension to five years; Postdoctoral Fellow normally two years, possibility of extension to three years. **APPLICATIONS** should be submitted in duplicate to the Registrar, The Australian National University, GPO Box 4, Canberra ACT2601, Australia, quoting reference number and including curriculum vitae, list of publications and names of at least three referees. The University reserves the right not to make an appointment or to appoint by invitation at any time. Further information is available from the Registrar, or from Appointments (36192), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.

**THE UNIVERSITY IS AN  
EQUAL OPPORTUNITY  
EMPLOYER**  
(W6024)A

**ANATOMIST**

**The Department of Anatomy,  
University of Saskatchewan,  
College of Medicine,**

invites applications for a faculty appointment at the rank of Assistant Professor. Applicants should have post-doctoral experience with a strong research program in any area of anatomical sciences; however, research in functional anatomy is preferred. The successful candidate will be responsible for teaching gross and neuroanatomy to Physical Therapy students. In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents.

Application, including curriculum vitae, names of three referees, and an outline of proposed research and previous teaching experience should be submitted to: **Dr. G. D. Burkholder, Department of Anatomy, College of Medicine, University of Saskatchewan, Saskatoon, Saskatchewan, Canada, S7N 0W0.** (NW3550)A

**PROTEIN CHEMIST**

Successful applicant will purify, analyze and identify proteins, will study physico-chemical properties of proteins by spectroscopy, calorimetric, electrophoretic and chromatographic methods, will conduct research to determine interactions between proteins and non-protein compounds. Minimum requirements. Master Degree in biochemistry or related field with one year experience as a protein chemist and one year experience with computer analysis of protein structure and with multicomponent analysis of derivative spectra of proteins. Salary \$18,852 year, 40 hours a week, 8 am - 5 pm. Please apply to: **Wyoming State Employment Service, 112 South 5th Street, Laramie, Wyoming 82070.** Refer to Job Order #WYO-201311. N(W3570)A

**UNIVERSITY OF CAMBRIDGE  
DEPARTMENT OF BIOCHEMISTRY  
SENIOR TECHNICAL OFFICER**

Senior Technical Officer to take up appointment on 1 October 1989. Applications invited from experienced NMR spectroscopists. The successful candidate will be expected to oversee the high-field NMR facilities located within the Department.

Salary on scale £13,365-£19,310.

Further information from **Secretary of Appointments Committee for Senior Technical Officers, General Board Office, The Old Schools, Cambridge CB2 1TT.** Applications (10 copies) with curriculum vitae and names of three referees by 26 April 1989. (8897)A

publique du Canada

## ***Biologists (BI-04)***

Health and Welfare Canada  
Health Protection Branch  
Ottawa, Ontario

The Bureau of Biologics requires two experienced scientific professionals to head two different areas within the Bureau.

### ***Bacterial Antigens and Antisera Section***

***Reference number: S-88-31-8119-47JG-G26***

As a Biologist with the Bureau, you will direct the activities of this Section. This involves regulatory control testing and evaluation of the safety and efficacy of various bacterial vaccines and antisera, as well as other biological drugs prepared with biotechnology for human use in the prevention and treatment of diseases. You will also direct and coordinate development research programs on the above-mentioned drugs.

Requirements include graduation with a doctoral degree from a recognized university in a biological science or a lesser degree with evidence of research experience. You must also possess laboratory and research experience in microbiology, molecular biology and immunology. Knowledge of English is essential.

### ***Immunology Section***

***Reference number: S-89-31-5221-47JG-G26***

As a Biologist with the Bureau, you will oversee the activities of this section. Such a responsibility involves regulatory control testing and evaluation of the safety and efficacy of various biological drugs (hormones, enzymes, allergenic products) prepared by different production methods including biotechnology. We will rely on you to act as a consultant in the appraisal and evaluation of new drug submissions and to evaluate operating procedures of Canadian and foreign pharmaceutical manufacturers. You will also direct and coordinate development research programs on the above-mentioned drugs.

Education includes graduation with a doctoral degree from a recognized university in a biological science or a lesser degree with evidence of research experience. You must also possess laboratory and research experience in biochemistry and immunology. Experience in molecular biology and microbiology would be a definite asset. Knowledge of English is essential.

***We offer*** a salary ranging from \$48,139 to \$55,591 commensurate with your qualifications and experience.

Please forward your résumé and/or application form, quoting the appropriate reference number to: ***Joan Girling, (613) 996-8054, Public Service Commission of Canada, National Capital Region, 171 Slater Street, Ottawa, Ontario K1A 0M7.***

***Closing Date:*** 31 May 1989

Public Service Commission of Canada is an equal opportunity employer

## INSTITUTE OF BIOTECHNOLOGY, UNIVERSITY OF HELSINKI RESEARCH DIRECTORS

The Institute of Biotechnology, University of Helsinki, is a new inter-faculty research unit with a special Ph.D. training program. At present, about 50 persons are working at the Institute, which has an annual budget of about USD 2.5 million.

The Institute will focus on basic research in different fields of molecular biology essential for the development of modern biotechnology. The research will be carried out in programs led by the Director of the Institute and Research Directors, who have the title of Professor.

The Institute has modern facilities for molecular and cell biology. It has and will have funds available for special equipment needed in new research programs, such as X-ray crystallography.

Applications are invited for research directors in the general field of molecular biology, preferably from those with training in:

- **Plant Molecular Biology**
- **Microbiology**
- **Biological Structures (Crystallography, Electron Microscopy)**
- **Developmental Genetics**

The research directors are appointed for a 5-year period (renewable) but can be made permanent for special reasons. The applicants should hold a Ph.D. or an equivalent degree, a substantial publication record and experience in directing scientific research. The salary is at the level of university professor in Finland (FIM 175,000-225,000; equivalent to USD 41,000-52,000).

Applications should be addressed to the **Board of the Institute of Biotechnology, Registrars Office of the University of Helsinki, Hallituskatu 8, SF-00100 Helsinki, Finland.** The applications should be at the University of Helsinki not later than May 31st, 1989.

Applications should include:

- 1) **curriculum vitae**
- 2) **list of publications 1980-1989**
- 3) **reprints of publications 1985-1989**
- 4) **a 5-year research plan**, with an estimation of the personnel required and possible plans for financing
- 5) **date when the applicant is available**

The Research Directors will be appointed by the Chancellor of the University after consultation with the Scientific Advisory Board of the Institute. The positions will be filled during the autumn of 1989.

For further information please contact Prof. Lauri Saxen (Chairman of the Board; telephone +358 0 4346433) or Prof. Helge Gyllenberg (Acting Director; telephone +358 0 4346041 or telefax +358 0 4346028).

W(6031)A

## THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY

### POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post, commencing as soon as possible, for a fixed term of 36 months, to study the actions and metabolism of extracellular ATP in human articular cartilage.

The project is funded by a grant from the Wellcome Trust to Dr A M Caswell and Professor R G G Russell (Department of Human Metabolism and Clinical Biochemistry, University of Sheffield Medical School).

Applicants should have a PhD or equivalent relevant experience. Expertise in tissue culture techniques advantageous.

Salary on the RA IA scale (£9865-£11070) according to qualifications and relevant experience.

Informal enquiries may be made to Dr A M Caswell (tel (0532) 333114).

Application forms and further particulars may be obtained from and completed applications forwarded to the **Registrar, the University, Leeds LS2 9TJ** (tel (0532) 333963 — direct line), quoting reference number 83/94.

Closing date for applications\* 27 April 1989. (8933)A

## THE AFRC INSTITUTE OF HORTICULTURAL RESEARCH

EAST MALLING

Scientific Officer (Band II/III)

A Scientific Officer is required in the Plant Physiology Department to assist the Head of Department in the development of existing biochemical research programmes, especially on plant hormone receptors.

Qualifications: Honours degree or equivalent in Biological Sciences with relevant post-qualifying experience (Band II); Ordinary Degree, HNC, HND or equivalent (Band III). Working experience with modern biochemical techniques an advantage.

Salary: In range £8,574-£10,994.

Further details and application form from the Personnel Officer, Bradbourne House, East Malling, Maidstone, Kent ME19 6BJ quoting Ref. 57/EM. Closing date 27th April 1989.

The Institute of Horticultural Research is an Equal Opportunities Employer. (8925)A

## MOLECULAR GENETICIST

### LADY DAVIS INSTITUTE FOR MEDICAL RESEARCH

The Lady Davis Institute, a research department of the Sir Mortimer B. Davis-Jewish General Hospital, is seeking a molecular geneticist at the assistant/associate professor level. Applicants should hold Ph.D. and/or M.D. degree(s), have significant post-doctoral experience and the potential for developing a vigorous independent research program on gene expression at a locus involved in human disease. Preference will be given to candidates with M.D. degrees who are qualified and willing to spend 20% of their time in the Division of Genetics of the Department of Medicine.

Send curriculum vitae, statement of research goals and the names of three references to:

**Dr. Herbert M. Schulman, Acting Director**  
**Lady Davis Institute for Medical Research**  
**Sir Mortimer B. Davis-Jewish General Hospital**  
**Montreal, Quebec, Canada H3T 1E2**

(NW3549)A

## RESEARCH ASSISTANT PROFESSOR

There is an immediate opening at the level of Research Assistant Professor in the Department of Physiology, University of Florida, College of Medicine. Applicants should have expertise in the fields of cellular and molecular neuroendocrinology. They should be willing to develop their independent research programs and interact with existing faculty members in the areas of the molecular biology of angiotensin II and/or growth factors in the brain. Ph.D. and/or M.D. is required and postdoctoral experience would be advantageous, though is not essential. The salary shall be \$25,000.00-\$32,000.00 p.a., depending upon experience. Applications, including a C.V., a summary of research experience and the names and addresses of three (3) references should be sent to:

**Dr. Colin Sumners, Department of Physiology, University of Florida, College of Medicine, Box J-274, JHMC, Gainesville, FL 32610, USA**

(NW3554)A

## VIROLOGIST

A Virologist with an interest in antiviral research is being sought to play a major role in two funded research grants. The candidate will explore the active components of natural products found to be effective in vivo for their effect on the replication cycle and pathogenesis of hepadnaviruses. The successful candidate should have some knowledge of the molecular biology of hepadnaviruses, tissue culture techniques and animal models useful for the study of hepadnaviruses. Although the project is funded, the candidate, in time, will be encouraged to seek independent funding to pursue related research and become eligible for a tenure track position.

Please send curriculum vitae and letters of reference to: **Virologist Search Committee, c/o Personnel Dept., Fox Chase Cancer Center, 7701 Burholme Ave., Phil., PA 19111.**

*We are an Equal Opportunity Employer* (NW3564)A

## UNIVERSITY OF ST ANDREWS

Department of Biology and Preclinical Medicine

### LECTURESHIP IN BIOLOGY

Applications are invited for the above post from candidates with a strong research record in any area of Plant Biology. Candidates interested in Plant Molecular Biology and/or Pathology will be welcome provided that they have a broad background in Plant Biology.

The appointment is tenable from 1st October 1989 and the salary will be on either the Lecturer Grade A scale £9,260 to £14,500, or Grade B scale £15,105 to £19,310 per annum, initial appointment probably on the Grade A scale.

Further particulars and application forms are available from the **Director of Personnel Services, The University, College Gate, St Andrews, Fife KY16 9ANJ, to whom applications should be submitted not later than 25th April 1989.** (8906)A

# Research Scientist/Immunology FRANCE

**ROUSSEL-UCLAF** is a major pharmaceutical company involved in Chemistry and Biotechnology for pharmaceutical, veterinary and agricultural activities.

The Company is seeking an immunologist for its Biotechnology Department located in suburban Paris. The successful candidate will join a multidisciplinary group, and head a team of 2/3 technicians. The research programs of the group are focused on chemicals and cytokines with immunomodulatory properties.

Requirements include a Ph.D and 2/3 years relevant post-doctoral : international experience would be appreciated. Enthusiasm and communication skills are important qualities. A substantial experience in cellular Immunology will be determinant.

Send resume, list of publications and the names of three references in confidence n° 107/N to Claudine MAUSHART, 35, boulevard des Invalides, 75007 PARIS (FRANCE).

**ROUSSEL UCLAF** 

(W6018)A

CURRICULUM

## CENTRAL BIRMINGHAM HEALTH AUTHORITY RESEARCH ASSOCIATE (Clinical Chemistry)

Based in the Cell Culture/Tissue Laboratory, you will provide a service to the Molecular Biology and Immunoassay sections of the Wolfson Research Laboratories. Cell/Tissue Culture is a relatively new area of expertise and you will be expected to help run a rapidly changing, expanding and important section within the laboratories. Opportunities may exist for the successful candidate to obtain further qualification.

Application form and job description from **Personnel Department, Queen Elizabeth Hospital, Edgbaston, Birmingham B15 2TH** telephone 021 472 1311 ext 3003.

Additional information and informal visits may be arranged with the laboratory Manager, Dr. Wendy Ratcliffe ext 4560. Closing date 21.4.89.

*The Authority is Committed to Equal Opportunities in Employment.* (8927)A

## OXFORD UNIVERSITY NUFFIELD DEPARTMENT OF PATHOLOGY

### Project on the Spread of Cancer in the Human Body Research Assistant Grade 1B

Applications are invited from graduates with a good honours degree for a training position in a team studying basic cellular and molecular mechanisms by which malignant tumours spread (metastasise) to distant organs in the body. The challenge of the job is that it focuses directly on the major problem of cancer: namely the formation of multiple scattered secondary tumours and how to control their growth. Experience in cell biology, biochemistry/molecular biology/virology or genetics will be an advantage but not essential, if the candidate has other relevant practical expertise.

Starting salary up to a maximum of £11,070 on the University Research Staff 1B scale (£8,675-£13,365), depending on age and experience. The project is financed for 3 years by the Cancer Research Campaign and the post is vacant.

Further information may be obtained from:

**Dr. D. Tarin Nuffield Reader in Pathology Nuffield Department of Pathology John Radcliffe Hospital Headington, Oxford OX3 9DU**

[Telephone: Oxford (0865) 817797]

to whom applications with full c.v. and names of 2 referees should be submitted by 27-4-89.

*Oxford University is an equal opportunity employer.* (8888)A

## PROTEIN

### CRYSTALLOGRAPHER

Postdoctoral position open for cooperation on the X-ray analysis of photosystem I. Crystals diffract to 4Å (to be improved), facilities include area detector, rotating anodes, graphical displays, Vax computers.

Send c.v. to **Prof. W. Saenger, Institut für Kristallographie der Freien Universität, Takustr. 6, D-1000 Berlin 33 (FRG).** (W6019)A

## Biochemical and Electrophysiological Pharmacologists

Medicinal Research Centre  
Harlow, Essex

Beecham, one of the UK's leading pharmaceutical companies, has embarked on a major expansion of CNS research.

Consequently, we now have excellent opportunities for a high calibre CNS biochemical-pharmacologist and an electrophysiologist to work as part of large, multi-disciplinary project teams. We are particularly interested in individuals who hold a PhD and have had several years' experience of CNS electrophysiological and/or biochemical techniques.

However, we should also like to hear from people, both at PhD and BSc level, who have less experience, but a keen interest in CNS electrophysiological and biochemical techniques.

We offer excellent career prospects, a progressive salary structure which recognises personal achievement, and the comprehensive range of benefits associated with a large company: including a non-contributory pension, free life assurance, company bonus and flexible working hours. Relocation assistance will be provided, where appropriate.

For an application form, please telephone: Harlow (0279) 622022 during office hours, or our 24-hour answering service on (0279) 622030. Alternatively, send your full CV, indicating your present salary level and quoting reference 20/89 to the Personnel Manager, Beecham Pharmaceuticals Research Division, Medicinal Research Centre, Coldharbour Road, The Pinnacles, Harlow, Essex CM19 5AD.

## DEAN GRADUATE SCHOOL OF BIOMEDICAL SCIENCES

As part of a plan to enhance its effectiveness and impact as a major research center, The University of Medicine and Dentistry of New Jersey seeks an accomplished Scientist as Dean of its Graduate School of Biomedical Sciences. The Graduate School consists of 14 departments on two campuses offering programs leading to the Ph.D., M.D./Ph.D. and D.M.D./Ph.D.

The successful candidate will have a Doctoral degree in an appropriate discipline plus a track record of substantial research activity sufficient for appointment as a tenured Professor. Administrative experience is desirable.

Review of applications will begin immediately. The University will continue to accept applications until the position is filled. Applicants should send a complete curriculum vitae and a brief letter of interest to: **Harvey Ozer, M.D., Search Committee Chair, Chairman, Department of Microbiology and Molecular Genetics, UMDNJ-New Jersey Medical School, (N), 185 South Orange Avenue, Newark, NJ 07103-2757.**

The UMDNJ is an Affirmative Action/Equal Employment Opportunity Employer M/F/H/V.

(NW3574)A

## UNIVERSITY OF BIRMINGHAM FACULTY OF MEDICINE AND DENTISTRY RESEARCH ASSOCIATE IN MOLECULAR MECHANISMS OF THYROID HORMONE ACTION

Applications are invited for the post which has been funded for 2 years. The appointee would join an established programme of molecular biology in endocrinology within the Department of Medicine. The post specifically involves the study of molecular mechanisms of thyroid hormone action; techniques to be used include cell culture, plasmid preparation and cDNA/mRNA hybridisation assays. Applicants should be graduates in a biological subject. Previous experience in molecular biology is not essential.

Starting date: July 1989 or as soon as possible thereafter. Salary on the Research Associate scale £8,675 – £11,680 plus superannuation. Informal enquiries to Dr J A Franklin on 021-472 1311 extension 3928 or 3361. Application forms from the Medical School on 021-414 4051 quoting reference RA/END/JF/1969. Applications (3 copies) to be returned to the **Senior Assistant Registrar, Medical School, University of Birmingham B15 2TT by 27th April 1989.**

An Equal Opportunities Employer (8917)A

## THE LONDON HOSPITAL MEDICAL COLLEGE (University of London) Postdoctoral Protein Biochemist (plus Honorary Lectureship status for suitable appointee)

Applications are invited for a three year appointment, funded by the Arthritis and Rheumatism Council, to study the oxidative/peptolytic inactivation of alpha-1-antitrypsin in rheumatoid synovial fluid and the potential for anti-inflammatory therapy with recombinant alpha-1-antitrypsins. The project is linked with Professor R W Carrell, Cambridge University.

The position is available now and the salary will be £16,150 – £20,960 inclusive of London Weighting.

Intending applicants should obtain further particulars of the post from Dr Paul Winyard, (Tel: 01-377 7763) or Professor David Blake (Tel: 01-377 7765). CV and names and addresses of two referees should be sent to **Dr P G Winyard, The Inflammation Group, Arthritis and Rheumatism Council Building, London Hospital Medical College, 25-29 Ashfield Street, London E1 1AD within 14 days.** (8895)A

## UNIVERSITY OF OXFORD NUFFIELD DEPARTMENT OF PATHOLOGY POST-DOCTORAL RESEARCH ASSISTANT

A post-doctoral research assistant (1A) is required to investigate the role of respiratory viruses in Sudden Infant Death (Cot Death). The project will involve developing the PCR for detection of specific viral RNA sequences in clinical samples and localisation of these sequences by in situ hybridisation. A knowledge of any of the following would be an advantage, molecular biology, tissue culture, immunohistology and in situ hybridisation.

The post is funded by the Foundation for the study of Infant Deaths for 3 years. Starting salary within the range £9,865-£12,760 dependant on age and experience.

Applications with a full C.V. and the names and addresses of two referees should be sent to: **Dr. K. Fleming, Nuffield Department of Pathology, Level 1, John Radcliffe Hospital, Headington, Oxford: Tel (0865) 817476, from whom further details are available.** Closing date for applications: 27-4-89.

Oxford University is an equal opportunity employer. (8887)A

## PUBLIC HEALTH LABORATORY SERVICE BOARD

PHLS CENTRE FOR APPLIED  
MICROBIOLOGY & RESEARCH  
DIVISION OF BIOTECHNOLOGY  
MICROBIOLOGIST

A graduate technician is required to join the Thermophile Research Section. The successful applicant will be involved in genetic and physiological studies of a wide range of thermophilic microorganisms.

This appointment will be at Basic Grade Microbiologist, with a salary range of £7378-£11073.

NHS terms and conditions

Candidates wishing to informally discuss the post should contact Dr R. J. Sharp, tel: Idmiston (0980) 610391, ext 443.

Application forms can be obtained from the Personnel Officer, PHLS Centre for Applied Microbiology & Research, Porton Down, Salisbury, Wilts SP4 0JG. Tel: (0980) 610391, to whom completed forms should be returned by 21st April 1989 quoting Post No. 0808. (8911)A

### Part-time Technician

Technician with experience in histological procedures required to join multidisciplinary team that is using novel immunological techniques to monitor the interaction of tumours with chemotherapeutic drugs and monoclonal antibodies. The work which is based on the use of immunocytochemical techniques will include the use of image analysis for the detection of drug induced damage to the DNA of tumours, and the topoisomerases I and II. In addition the group is interested in the interaction *in vivo* of monoclonal antibodies with growth factor receptors on human tumours that overexpress these receptors.

The post which is part time (30 hours/week) would be suitable for a graduate in a biological science or other suitably qualified person with an interest in the use of histological techniques. While experience in immunocytochemical methodology would be an advantage it is not essential.

Salary will be in the range of £7004 to £9347 for a 30 hour week.

Applicants are advised that smoking is prohibited in the majority of the Institute's premises.

To apply, please submit a Curriculum Vitae, in duplicate, with names and addresses of two referees to the **Personnel Officer, 17A Onslow Gardens, London SW7 3AL** quoting reference 4.89.T.N.1 (8916)A

**Max-Planck-Institut für molekulare Genetik**

UNIVERSITY OF LONDON

## Sir William Dunn Chair of Experimental Pathology

**Tenable at the United Medical and Dental Schools of Guy's and St Thomas's Hospitals (Guy's Campus)**

The Senate invites applications for the above established Chair which became vacant on the retirement of Professor Colin Adams on 30 September 1988.

The main responsibility of the post is to promote research within the broad field of experimental pathology. Applicants will be considered with an interest in any branch of basic biological science including molecular pathology, cell biology, immunopathology, molecular oncology or neurobiology. The professor may or may not be medically qualified. The successful candidate will be expected to organise, supervise and actively participate in research with members of the Division of Histopathology as well as other Divisions of the United Schools.

The professor will be expected to take an active part in teaching within the pathology courses for undergraduate and postgraduate students especially in the general principles of cellular pathology.

Applications (10 copies) should be submitted to the **Teachers' Section, (N) University of London, Malet Street, London WC1E 7HU**, from whom further particulars should first be obtained.

Prospective candidates wishing to visit the department should contact Professor D A Levison. Tel: 01-407 7600 extension 2591.

Closing date 7 May 1989.

(8896)A

### CANCER RESEARCH CAMPAIGN POSTDOCTORAL SCIENTIST

in the MRC Clinical Oncology and Radiotherapeutics Unit, Cambridge

Applications are invited for a three-year postdoctoral appointment funded by the Cancer Research Campaign and available immediately.

The project involves the study of factors controlling the amplification and expression of genes related to cytotoxic drug resistance in both *in vitro* and *in vivo* tumour model systems. Candidates should have experience in mammalian cell culture and/or molecular biology techniques including *in situ* hybridization.

Enquiries to Dr Peter Twentyman, Tel: (0223) 248011 ext.

Salary £10,460 to £12,760 per annum (under review) on the MRC Non-Clinical Scientific scale.

Applications, including a curriculum vitae and names of 2 professional referees, should be sent quoting reference CRC to:—

**The Personnel Officer**  
MRC Centre  
Hills Road  
Cambridge  
CB2 2QH

**MRC**

to arrive not later than 21 April 1989.

*The Medical Research Council is an Equal Opportunities Employer.* (8894)A

UNIVERSITY OF WARWICK

### LECTURER IN EXPERIMENTAL PHYSICS

Applications are invited for a Lecturer post tenable from 1 October 1989. The person appointed will have research experience in experimental condensed matter Physics. Some preference may be given to persons with experience in the fields of Ceramics and/or Surface Physics. The initial appointment will be on the Lecturer 'A' scale: £10460-£14500 pa (subject to review), with progression to the Grade 'B' scale (to £19310) subject to satisfactory progress.

Application forms and further particulars from the **Personnel Office, University of Warwick, Coventry CV4 7AL (0203 523627)** quoting Ref No 34/A/88/14 (please mark clearly on envelope). Closing date for applications is 5 May 1989.

*An Equal Opportunities Employer*

(8889)A

**INSTITUTE OF PLANT SCIENCE RESEARCH  
CAMBRIDGE LABORATORY  
Molecular Biologist**

The Laboratory is seeking to appoint a Post-doctoral Fellow to carry out research on the genetic engineering of novel pathogen resistances in potato. This work will involve gene isolation and characterization, expression vector construction, and plant transformation. The position would suit someone with a background in genetics, biochemistry or botany, with a particular interest in the application of genetic engineering to crop plants. Full training will be given

The post is funded for two years. Initially the successful applicant will be based at the Cambridge Laboratory but in March 1990 will transfer to new laboratories at the John Innes Institute, Norwich.

The salary will be on the HSO scale £10,026 – £13,400, with a non-contributory superannuation scheme.

Applications with curriculum vitae and names and addresses of 3 referees should be sent to **Mrs L Cliff, Personal Officer, IPSR Cambridge Laboratory, Maris Lane, Trumpington, Cambridge CB2 2JB**, quoting reference **MG/357**, by **21st April 1989**.

*The Institute is an Equal Opportunities Employer* (8915)A

**UNIVERSITY OF GLASGOW**

**Department of Electronics and Electrical Engineering  
Lecturer in Bioelectronics**

This lectureship provides a remarkable opportunity to join a team of electronic fabrication engineers, cell biologists and biochemists who are attempting to explore the interface between biological moities and electronic circuits with the ultimate ambition of progress in embryology, understanding neural networks and development of prosthetic devices. The Group enjoys substantial support from BP Venture Reserch Unit and SERC.

Honours degree lecture courses in Bioelectronics are being developed in conjunction with University Departments of Life Sciences.

Candidates should have an honours degree in electronics, electrical engineering or physics: postgraduate experience in bioelectronics would be helpful though not essential. This appointment arises through expansion of the Department.

Salary will be on the scale for Lecturers within the range £9260 – £19310 p.a. (under review). Placement will be according to experience and qualifications.

Further particulars may be obtained from the **Academic Personnel Officer, University of Glasgow, Glasgow G12 8QQ**, with whom applications (8 copies) should be lodged by **24 April 1989** giving the names and addresses of three referees. Applicants wishing to visit the Department would be welcome to do so by arrangement with Professor John Lamb.

In reply please quote Ref 6300/1

(8936)A

**McMaster University  
CHAIRMAN,  
DEPARTMENT OF BIOLOGY**

Applications are sought for the position of Chairman, Department of Biology. The candidate should have an outstanding research record in developmental biology and possess excellent leadership qualities.

The appointment is available July 1, 1989, and will be at the rank of Associate Professor or Professor, salary and rank to be commensurate with qualifications and experience. Applications should include a detailed curriculum vitae and the names of three referees. Applications or requests for further information should be addressed to:

**Dr R.F. Childs, Dean of the Faculty of Science  
McMaster University, Hamilton, Ontario, L8S 4K1**

\* In accordance with Canadian immigration requirements, this advertisement is directed to Canadian citizens and permanent residents of Canada. McMaster is an equal opportunity employer. (NW3562)A

**POSTDOCTORAL  
RESEARCH FELLOW**

**UEA  
NORWICH**

Applications are invited for the above post in the School of Biological Sciences, commencing 1st July 1989 or as soon as possible thereafter for a fixed term of 36 months, to study the nature and significance of electrical phenomena associated with the systemic induction, by wounding, of proteinase inhibitors in tomato plants. Applicants should have a PhD or equivalent experience, preferably in electrophysiology, but other relevant subject areas will be considered. Previous experience of work with plants is not essential. Salary will be on the RA1A scale (£9,845-£11,680) according to qualifications and relevant experience. The project is funded by a grant from the Agricultural and Food Research Council to Drs. J. F. Thain and D. C. Wildon, to whom enquiries should be addressed (Tel: (0603) 56161 ext. 2257).

Applications, giving full curriculum vitae and the names of two referees, should be sent to **Drs. J. F. Thain and D. C. Wildon, School of Biological Sciences, University of East Anglia, Norwich, NR4 7TJ**. Closing date for applications 5th May 1989. (8929)A

**DEPARTMENT OF SURGERY,  
UNIVERSITY OF EDINBURGH  
and SOUTH-EAST REGIONAL  
CENTRE OF THE SCOTTISH  
NATIONAL BLOOD  
TRANSFUSION SERVICE  
RESEARCH FELLOW  
and PART-TIME  
RESEARCH ASSISTANT**

Applications are invited for the above posts which are funded by a grant awarded to Dr. K. James, Dr. C. V. Prowse and Dr. D. B. L. McClelland under the MRC AIDS Directed Programme. The aim of this project is to develop human monoclonals to HIV for use both in AIDS research and patient management.

Preference will be given to applicants with hybridoma, virological and immunoassay skills.

The posts are funded for three years with starting salaries according to age and experience as follows:—

Research Fellow (Scale 1A) up to £11,680

Research Assistant (Scale 1B) half time — £5,230

For further details of these posts contact either Dr. K. James (667 1011, ext. 2287) or Dr. C. V. Prowse (229 2585 ext. 298). Formal applications in writing with a full C.V. and the names and addresses of two referees should be sent to **Dr. Keith James, Department of Surgery, University Medical School, Teviot Place, Edinburgh EH8 9AG**. Closing date — April 30 1989.

## STAFF SCIENTISTS PROTEIN DESIGN LABS

Protein Design Labs is a biotechnology company based on the concept of protein engineering. We are applying recent developments in molecular biology, immunology, protein chemistry and computer modeling to create novel proteins for the treatment of human disease, especially autoimmune disease and cancer. Our first product, a humanized antibody for the prevention of organ transplant rejection, will enter clinical trials soon. We have an outstanding group of scientists and scientific advisors, and an excellent location near Stanford University.

Additional staff scientists and research assistants are needed in all areas. We offer competitive compensation, stock in our growing company, and an opportunity to do exciting science.

**Send CV to Dr. Cary Queen, Protein Design Labs, 3181 Porter Drive, Palo Alto, CA 94304. EOE.**

(NW3579)A

## DEPARTMENT OF VETERANS AFFAIRS

### VETERANS HEALTH SERVICES AND RESEARCH ADMINISTRATION

## DIRECTOR MEDICAL RESEARCH SERVICE

The Department of Veterans Affairs invites applications for the position of Director, Medical Research Service. The Medical Research Service currently has a budget of about \$200 million and supports biomedical and behavioural sciences research of over 2500 VA scientists, 70 percent of whom are physicians. It is strongly committed to support of patient-oriented research across the entire spectrum from basic science to clinical applications of new knowledge. The Director is responsible for policy development, peer review management of all investigator-initiated research studies and budget formulation and distribution. Candidates are expected to be nationally recognized scientists and they must have an established record of scholarly achievement. The position is only open to U.S. citizens who hold an M.D. degree. Salary is \$75,500 with additional special pay up to \$24,000.

Qualified applicants are invited to send a curriculum vitae, bibliography and the names, addresses and telephone numbers of three respondents by 15 May 1989 to: **Richard J. Greene, M.D., Ph.D., Assistant Chief Medical Director for Research and Development (15), Department of Veterans Affairs, 810 Vermont Avenue, N.W., Washington, D.C. 20420.**

**Veterans  
Administration**

(NW3541)A

### POSTDOCTORAL FELLOW/ INSTRUCTOR/ASSISTANT PROFESSOR Requirements: Ph.D. degree in molecular and/or cell biology

The Department of Medicine at Brigham and Women's Hospital and Harvard Medical School, Boston, MA is seeking applicants with a Ph.D. degree in molecular and/or cell biology for a position in the Molecular and Cellular Vascular Research Laboratory. The laboratory employs a multidisciplinary approach with emphasis on qualifications. Recognized excellence in basic investigation is deemed essential. Position available: July 1, 1989. Annual Salary: to be negotiated. Send curriculum vitae and references to:

**Dr. Victor J. Dzau, M.D., Chief, Molecular and Cellular Vascular Research Laboratory, Brigham and Women's Hospital, 75 Francis Street, Boston, MA 02115. Telephone: (617) 732-6628; FAX: (617) 732-6961.**

(NW3553)A

### FULL-TIME POSTDOCTORAL POSITION OR ASSISTANT RESEARCH PHYSIOLOGIST POSITION

Available immediately for two years (with possibility for renewal), for a biophysicist trained in cellular electrophysiology to study calcium action in neurons. Annual salary \$23,196 - \$28,920 for postdoc, \$36,600 - \$45,700 for Assistant Research, depending on experience. Photosensitive calcium chelators will be used to probe the role of calcium in transmitter release and plasticity at central and peripheral synapses, and in activating ionic currents. Experimental preparations include neuromuscular junction, ganglionic and isolated neurons, and the squid giant synapse using a local squid holding facility. A new calcium imaging system on an upright microscope is available to trace changes in presynaptic calcium during electrical activity, and explore ionic mechanisms of facilitation and potentiation.

Before 11 May 1989, send resume, reprints, and two names of references to: **Dr. Robert Zucker in the Neurobiology Division of the newly designated Molecular and Cellular Biology Department, University of California, Berkeley, CA 94720.**

*An Equal Opportunity Affirmative Action Employer*

(NW3545)A

## POSTDOCTORAL POSITIONS

The CNRS has created

a

### PLANT SCIENCE INSTITUTE (INSTITUT DES SCIENCES VEGETALES)

on its Gif Research Centre (the main CNRS Campus for biological research in the Paris area). Excellent facilities for molecular biology and plant work (growth cabinets, greenhouses, etc.) will be provided. From late Spring 1989 the ISV will start operation in the completely renovated laboratories. The aim of the ISV is to conduct research in the field of molecular and cellular biology of plant growth, differentiation and development, taking into consideration also potential applications. Several of the already selected programmes will focus on the recognition and transduction of signals leading to these processes in microbe-plant interactions. Adam Kondorosi has been named director and the establishment of research groups, headed among others by Jacques Tempé, Bruno Gronenborn and Eva Kondorosi, is underway.

Two postdoctoral positions for plant molecular biology research in the field of molecular biology of microbe-plant interactions are available. Applications should be sent to: **the Director of the Institut des Sciences Vegetales, CNRS, Avenue de la Terrasse, F-91198 Gif-sur-Yvette Cedex, France. (W6037)A**

### University of Manchester, Department of Chemistry Postdoctoral Research Associate in Molecular Modelling

Applications are invited for a three year Postdoctoral Research Associate Post funded by Shell Research Limited. The successful applicant will study aspects of molecular similarity and molecular recognition on theoretically determined reaction pathways. Experience in the development and use of quantum mechanical codes is desirable for this position. The initial salary will be up to £14,000 p.a. **Further details and application form may be obtained from Professor I.H. Hillier, Department of Chemistry, University of Manchester, Manchester M13 9PL.**

(8937)A

## FACULTY POSITION — X-RAY CRYSTALLOGRAPHY

The Department of Biochemistry, Medical School at the University of Minnesota invites applications for a tenure-track faculty position at the Assistant or Associate Professor level. Candidates with professional distinction in research and writing and demonstrated effectiveness in teaching and advising will be considered for an Associate Professor position. Candidates demonstrating involvement in quality research accepted or published in peer-reviewed journals will be considered for an Assistant Professor position. Applicants should have a Ph.D. degree with expertise in x-ray crystallography and structural analysis of macromolecules. The successful applicant will be part of a group of scientists working in structural biology associated with the William F. Dietrich Chair program. The Structural Biology group complements a core of biophysical scientists in several departments in the Medical School and in the College of Biological Sciences. These departments maintain strong graduate programs in biophysics and molecular biology. The new opening includes ready access to state-of-the-art x-ray diffraction facilities and the Minnesota Supercomputer Institute. Applications must be postmarked no later than June 1, 1989. Send curriculum vitae, a concise plan for future research, and the names of three references to:

**Leonard J. Banaszak, Center for Structural Biology  
Department of Biochemistry, Medical School  
4-225 Millard Hall, 435 Delaware St. S.E.  
University of Minnesota  
Minneapolis, MN 55455**

The University of Minnesota is an equal opportunity educational employer, and specifically invites and encourages applications from women and minorities.

(NW3567)A

### POSTDOCTORAL RESEARCH ASSOCIATE

position available summer/fall 1989 in time-resolved fluorescence spectroscopic studies of cell membranes and lipid bilayers with focus on drug-membrane and protein-lipid interactions.

Applicants should be recently qualified Ph.D.'s with a general background in either **physical chemistry** or **biophysics** with interest or experience in fluorescence spectroscopy, lipid bilayers and cell membranes. The department has a large, well equipped membrane research group with interests in membrane physical properties and related fields.

Send CV and the names of three references to: **Dr. C. D. Stubbs, Department of Pathology and Cell Biology, Thomas Jefferson University, Philadelphia, PA 19107.**

Equal Opportunity Employer  
(NW3573)A

### MURDOCH UNIVERSITY Perth, Western Australia POSTDOCTORAL RESEARCH FELLOW — THERMODYNAMIC MODELLING SCHOOL OF MATHEMATICS AND PHYSICAL SCIENCES

Applications are invited for the position of Postdoctoral Research Fellow to assist with a research project in Thermodynamic Modelling. The work involves the theoretical and practical development of a computer model for the control of a large scale metal production plant in Kalgoorlie, Western Australia. The project will involve work mainly on campus in Perth but also on-site in Kalgoorlie. Accommodation in Kalgoorlie will be provided free of charge.

A graduate in chemistry is preferred but graduates in chemical engineering or metallurgy will be considered. Fortran Programming ability and a knowledge of chemical thermodynamics are required.

The position is available for two years. (Ref 1134)

Further information may be obtained from Dr Peter May (tel (09) 332 2203, fax (09) 332 2507).

Salary: A\$26,617 to A\$30,360 per annum.

Applications in duplicate, quoting reference number, including full personal particulars, details of tertiary qualifications and experience, a curriculum vitae and academic transcript and the names and addresses of two professional referees should reach the Chief Personnel Officer, Murdoch University, Murdoch, Western Australia, 6150 by Friday 19 May 1989.

Applicants resident in the United Kingdom, Europe or Africa, at the time of application should also forward One further copy to Appointments (36228), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF, UK.

Murdoch University is an Equal Opportunity Employer.  
(W6032)A

### FACULTY OF MEDICINE AND HEALTH SCIENCES

UNITED ARAB EMIRATES  
UNIVERSITY

### ASSISTANT/ASSOCIATE PROFESSOR/PROFESSOR\* DEPARTMENT OF MEDICAL ANATOMY

The Faculty of Medicine and Health Sciences is now in its third year of operation having accepted its first class of medical students in September 1988 following two years of premedical study. The Faculty of Medicine utilizes two affiliated hospitals in Al Ain Tawam Hospital and Al Ain Hospital, with a total of 1050 beds. Currently housed in temporary facilities, it is in the process of finalizing plans for the construction of a teaching and research facility of international stature to be completed in 1991. The language of instruction is English.

Candidates applying for these positions must have demonstrated interest in teaching and research. Emphasis is placed upon candidates with an interest and experience in a problem solving approach to medical education. In addition, candidates must possess a medical degree and/or PhD degree as appropriate to post or an equivalent higher professional degree from an accredited university or institution of higher learning. Preference will be given to candidates possessing a higher qualification.

Salary and liberal benefits are offered, commensurate with qualifications and level of responsibility. If you are seeking professional growth and an excellent work environment, send detailed resume, copies of certificates and passport and the names of three referees familiar with recent work history to: The Dean, Faculty of Medicine and Health Sciences, UAE University, PO Box 15551, Al Ain, United Arab Emirates.

\*The rank of Professor does not carry Chairmanship with it. Applications should be received within one month following publication date. All positions will remain open until filled. W(6029)A

**Department of Biology  
SENIOR RESEARCH OFFICER**

Applications are invited from postdoctoral candidates for a post of Senior Research Officer to take part in a project funded by the SERC for three years to develop immunological methods for large scale fractionation of cells. Experience of monoclonal antibody production is required. The starting salary will be up to £11,680 per annum on Grade 1A. Further support may be obtained from industrial collaborations.

Applications (three copies), including a curriculum vitae and the names and addresses of two referees, should reach the Registrar (R/864/N), University of Essex, Wivenhoe Park, Colchester, CO4 3SQ, from whom further particulars may be obtained, by **27th April 1989**. (8928)A

**UMIST**

**Department of Biochemistry and Applied Molecular Biology  
Lignocellulose Degradation by Actinomycetes**

**RESEARCH ASSOCIATE**

A postdoctoral position is available for three years to participate in a programme to investigate novel extracellular enzymes involved in the degradation of lignocellulose by actinomycetes. The opportunity exists to combine an interesting research programme with wider commercial applications. Applications from candidates with a particular interest in lignocellulose structure and degradation products would be welcomed. Experience of analytical techniques such as HPLC would be an advantage. Commencing salary will be within the scale: £9,865-£15,720 per annum. Letters of application, including full curriculum vitae and the names of two referees, should be sent to: **Professor P M A Broda, Department of Biochemistry and Applied Molecular Biology, UMIST, P O Box 88, Manchester M60 1QD**, to whom informal enquiries may be made on 061 236 3311 ext 2119. Please quote reference BIO/R/34. (8935)A

**Harvard Medical School  
Genetics Division at The Children's Hospital  
A Postdoctoral Position**

is available in Human Genetics. The candidate should have experience in molecular techniques. He/she will work on structural/functional aspects of the human sex chromosomes. The position is funded for at least two years. Please send CV and three letters of recommendation to: **Dr. Ulrich Muller, Division of Genetics, The Children's Hospital, 300 Longwood Avenue, Boston, MA 02115**.

Harvard Medical School is an Equal Opportunity/Affirmative Action employer. (NW3577)A

**Antisense RNA  
Regulation**

Postdoctoral position (Sept. 1, 89) in yeast molecular biology on use of antisense RNA for gene regulation. Experience in recombinant DNA required. Send C.V. and names of 3 references to: **Dr. G. H. Rank, Dept. of Biology, Univ. of Sask., Saskatoon, Sask., Canada, S7N 0W0**. (NW3551)A

**POSTDOCTORAL POSITION**

We are seeking an experienced membrane biochemist who will isolate the complete bacterial flagellar motor and determine its structure by electron microscopy. The Structural Biology Laboratory at Brandeis has extensive facilities for electron microscopy and image analysis, and will provide as part of this project training in these techniques. Inquiries and applications, including a CV and names of three references, should be sent to:

**Dr. David DeRosier, Rosensteel Basic Medical Sciences Research Centre Brandeis University,  
P.O. Box 9110, Waltham, MA 02254-9110**

UNIVERSITY OF ST ANDREWS  
DEPARTMENT OF BIOCHEMISTRY  
AND MICROBIOLOGY

### POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a 3-year SERC funded postdoctoral position to work on the molecular genetics of nitrite reduction in barley. Applicants should preferably have a background in molecular biology or genetics.

Starting salary within range £9,865 to £11,680 per annum, on the 1A scale.

Informal enquiries, and formal applications with a *Curriculum Vitae* and the names of two referees, should be sent to **Dr J L Wray, Plant Molecular Genetics Unit, University of St Andrews, Sir Harold Mitchell Building, St Andrews, Fife KY16 9TH**, (Tel 0334 76161 Ext. 7253). (8907)A

### POSTDOCTORAL POSITION, NEUROPHYSIOLOGIST.

Position available immediately to work on the neuronal basis of learning in invertebrate animals. Candidate should be experienced in extracellular and intracellular recording and will work in association with a group studying behavioral, pharmacologic, and immunocytochemical aspects of conditioning in crustacea (*J. Neurosci.* (88) B, 2907-2912). We offer an excellent benefits package and a salary of \$24,000 per year.

Please send C.V. and the names of two references to:  
**Prof. Richard D. Feinman, Department of Biochemistry, SUNY Health Science Center at Brooklyn, 450 Clarkson Avenue, Box 8, Brooklyn, NY 11203.**

## AWARDS

# Sandoz Prize for Immunology

The prize will be worth US \$ 100 000 (US \$ 20 000 personal recognition/US \$ 80 000 support for research programme), and will be sponsored by SANDOZ LTD., Basle, Switzerland with the purpose of encouraging research in all areas of immunology with special emphasis on clinical immunology, including autoimmune diseases, cancer immunology, immunity to infectious diseases, transplantation immunology and discoveries in immunology leading to therapeutical applications.

Members of the Jury are G. Ada, J.-F. Bach, T. Honjo, P. Marrak, H.O. McDevitt, J.J. van Rood, R. Zinkernagel, and two representatives of Sandoz Ltd. The prize will be awarded on the occasion of an important Immunology Meeting in 1990.

Applications in English should comprise a summary of the research work of 3-5 pages, curriculum vitae, bibliography, experimental original papers separate from reviews and chapters, and reprints of not more than 3 key published papers in English or with extended summaries in English.

Individuals and research teams are invited to submit their applications not later than 30th June, 1989 to Sandoz Prize for Immunology, P.O. Box 182, 4013 Basel, Switzerland.

## FELLOWSHIPS

## EUROPEAN SOUTHERN OBSERVATORY

Organisation Européenne pour des Recherches Astronomiques dans l'Hémisphère Austral Europäische Organisation für astronomische Forschung in der südlichen Hemisphäre

## FELLOWSHIP AT LA SILLA

A position is available at La Silla for a post-doctoral fellow with an interest in observational astronomy. Experience with IR instrumentation or optical photometry will be an advantage.

The successful applicant will be expected to spend not more than 50% of his/her time in support related activities and the rest of the time doing scientific research. The presence at La Silla will be for at least 150 nights per year. ESO fellowships are granted for a period of one year normally renewed for a second period and exceptionally renewed for a third and final year.

The facilities on La Silla consist of 15 telescopes including the SEST 15-m submillimeter antenna, and the new 3.5m NTT. The computing facilities comprise an HP1000 system with full image processing capabilities (IHAP), a VAX 11/750 mainframe, and three SUN 4/110 workstations for image processing (MIDAS).

Close to 20 astronomers, including staff members, fellows and students, work at La Silla. The research projects currently pursued by the astronomical staff at La Silla include low mass star formation (Herbig-Haro objects, molecular outflows, T Tauri stars), OH/IR stars, symbiotic stars and proto-planetary nebulae, coronal activity in late type stars, chemistry of molecular clouds, formation of massive stars and starburst activity, dynamics of elliptical galaxies, active nuclei, QSOs and gravitational lensing, and observational cosmology.

Applicants normally should have a doctorate awarded in recent years. The monthly basic salary will be not less than DM 4190 to which are added 7% for pension purposes and a non resident allowance of 30-45% as well as a mountain allowance of 5-10%. Applications should be submitted to ESO not later than May 15, 1989. Applicants will be notified in July 1989. The ESO Fellowship Application Form should be used and be accompanied by a list of publications. In addition, three letters of recommendation should be obtained from persons familiar with the scientific work of the applicant. These letters should reach ESO not later than May 15, 1989.

Enquiries, requests for application forms and applications should be addressed to: **European Southern Observatory, Fellowship Programme, Karl-Schwarzschild-Straße 2, D-8046 GARCHING b. München, Federal Republic of Germany** W(6026)E

## POSTDOCTORAL FELLOWSHIP

NIH Staff Fellow/Senior Staff Fellow position is available at the National Institute on Alcohol Abuse and Alcoholism, for studies of neurotransmitter and hormone receptors and their interactions with cytokines and growth factors. Preference is given to applicants with experience in molecular biology, protein purification and receptor biochemistry/pharmacology. Salary is commensurate with experience. Only U.S. citizens or permanent residents are eligible for this position.

Send CV and name of three references to:

DEPARTMENT OF HEALTH AND HUMAN SERVICES  
Public Health Service  
National Institute of Mental Health

## Extramural Research Staff Fellowship Program

The National Institute of Mental Health (NIMH) in the Alcohol, Drug Abuse, and Mental Health Administration (ADAMHA), Public Health Service announces a unique opportunity for both developing and well-established scientists to work closely with senior scientists and administrators in guiding its extramural research support programs. The Extramural Staff Fellowship Program will provide a limited number of fellowship appointments in the biomedical, neuroscience, behavioral, clinical and services research areas. Extramural staff fellowships are intended to give talented scientists at an early, mid-point, or senior level in their career an opportunity to participate in and bring new ideas to the scientific research supported at NIMH. Opportunities may also be available for extramural staff fellows to participate in the relevant research projects in collaboration with the Institute's intramural research program or with outside organizations. Fellows must hold an M.D., Ph.D., or equivalent degree. Salary will be in the \$29,000 to \$75,500 range, depending upon training, post-doctoral research experience, and the scope and complexity of the research skills required. Fellows would also be eligible for full Government benefits and leave. U.S. citizenship or permanent residency status is required. Appointments will be made for an initial period of up to two years, and may be extended. Positions will be located in Rockville, Maryland. Interested persons should contact either NIMH Director (Dr. Lewis Judd) or the Deputy Director (Dr. Alan Leshner) at 301-443-3673, or may submit a curriculum vitae in confidence to 5600 Fishers Lane, Room 17-95, Parklawn Building, Rockville, Maryland 20857.

ADAMHA is an Equal Opportunity Employer.

(NW3538)E

## UNIVERSITY OF OXFORD

## NUFFIELD MEDICAL RESEARCH FELLOWSHIP

A Nuffield Medical Research Fellowship, tenable for a fixed period of two years in the first instance with the possibility of renewal for a further and final fixed period of one year, will be available from 1 October 1989. The successful candidate (who will not normally be expected to have more than five years of experience after completing a medical qualification or a doctorate) will be required to carry out a research project in a clinical academic or medical sciences department of the University. Salary (under review) on the scale £13,470-£15,510 if medically qualified, or £9,865-£12,150 if not. The appointment will be held in conjunction with a Junior Research Fellowship at New College. Further particulars may be obtained from the

**Senior Assistant Registrar,  
The Medical School Offices,  
John Radcliffe Hospital,  
Headington, Oxford, OX3 9DU**

to whom applications (including details of the research project agreed with the head of department in which it would be carried out) must be sent by 5 May 1989. (8919)E

*The University is an Equal Opportunity Employer*

## EMBO

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION  
SHORT TERM FELLOWSHIPS  
in molecular biology

The European Molecular Biology Organization awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of application.

Applications for exchanges between laboratories within any one country cannot be considered. Fellowships involving transatlantic travel are awarded only in exceptional circumstances. Inquiries should be accompanied by a self-addressed adhesive label.

Application forms and further details may be obtained from **Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F.R.G.** (W5706)E

## INTERNATIONAL CANCER RESEARCH FELLOWSHIP

The Hayashibara Mutual Aid Fund, a non-profit making organization within the Hayashibara Group announces a fellowship program. Two awards will be made annually. Fellowship will be taken up at the newly opened Fujisaki Cell Center which is devoted for the basic and applied research related to the problems in human cancer. The fellowship is normally made for one year and is renewable for up to five years. The fellowship will be expected to commence within six months of the announcement of the awards. The awards are for high quality research work in one of the three categories described below.

1. Fundamental Leukemia-Lymphoma Research,
2. Cytokine-Lymphokine Research,
3. Hematopoietic Cell Cultures.

Qualified person who has a Ph.D., an M.D. or equivalent qualifications will be awarded on merit to suitably qualified research proposal and experiences. Additional information and application forms will be obtained from: **Jun Minowada, M.D., Director, Fujisaki Cell Center, 675-1, Fujisaki, Okayama 702, Japan.** (W5829)E

THE UNIVERSITY OF  
THE SOUTH PACIFIC

Alafua Campus, Western Samoa

FELLOWSHIPS IN THE  
INSTITUTE FOR  
RESEARCH, EXTENSION  
AND TRAINING IN  
AGRICULTURE (IRETA)

The following Fellowships are tenurable at the Institute (IRETA) which is centred with the School of Agriculture on the University's Alafua Campus in Apia, Western Samoa, and serves eleven Pacific Island nations in the Region. Citizens of EEC and ACP countries only are eligible to apply.

The vacancies are advertised pending final confirmation of funding which has been approved in principle but not finally confirmed yet.

Fellow in Plant Tissue Culture  
(Post 89/15)

A unit in Plant Tissue Culture has been set up within IRETA with the objective of providing a service to the Governments of the countries of the Region to facilitate the safe introduction, multiplication and dissemination of improved cultivars of commercial crops using tissue culture and to provide a germplasm store for some of the crops important to the region. The unit is working with Sweet Potato, Ipomea; Colocasia, taro; Banana, Vanilla and Coconut embryo tissue, and has all the basic facilities for this work. It is planned to expand the work and funds are available for the modification and equipping of culture and storage rooms and for a post quarantine screen house. The proposed plan of work includes the development of tissue culture procedures for other crops and the introduction where possible of local indexing of virus free materials together with training programmes and workshops for agriculture staff of the Region and students in the School of Agriculture.

Recruitment of a senior experienced Fellow who will be responsible to the Director of IRETA for the work of the unit is in progress. The successful applicant for this post will be responsible to the Senior Fellow and assist her or him with the programme. Applicants should possess a good first degree in Botany, Horticulture or Agriculture and some experience of tissue culture or a higher degree taken in the field of tissue culture.

## Fellow in Applied Statistics (Post 89/16)

The appointee will be responsible to the Director of IRETA for the provision of a statistical design and analysis service to the Agricultural Departments of the South Pacific Region and to undertake formal

and non formal teaching in experimental design and analysis and the use of microprocessors in the field of agricultural experimentation and survey. The Alafua campus has standardized on IBM computers and has IBM, AT and XT models for this work together with a network of six stations for teaching purposes and funds to extend this basic configuration. The University has at its Laucala Campus a Vax computer accessible by post and shortly by radio satellite data transfer.

Applicants should possess a good first degree in Agriculture, Science or Mathematics and a higher degree in Agricultural Experimentation and Statistics or Computing. Experience in the fields of experimental design and statistical analysis and in the use of microprocessors and the software appropriate to IBM machines is essential.

Salaries for the above positions will be in accordance with qualifications and experience in the following scales: Junior Lecturer WS\$24,353-WS\$27,324; Lecturer II WS\$28,414-WS\$31,793; Lecturer I WS\$32,917-WS\$44,735; Senior Lecturer WS\$46,166-WS\$53,946. The University also provides gratuity amounting to 15% of basic salary; appointment allowance; partly furnished accommodation at a rental of 12.5% of salary; and a contribution of 10% of basic salary towards an approved superannuation scheme. The University has also introduced a home currency option to members of staff who are based outside the home countries to assist them with exchange rate fluctuation. Appointment will be for a contract period of three years with a possibility of extension for a further two years.

Further information may be obtained from the Assistant Registrar (Staffing) at the University Laucala Campus, Suva, Fiji (Telephone 313900; Telex FJ2276; 1 (679) 301305).

Candidates should send THREE COPIES of their curriculum vitae with full personal particulars names and addresses of three referees and date of availability. In order to expedite the appointment procedure applicants are advised to ask their referees to send confidential reports direct to the University without waiting to be contacted. Applications should be sent to the Secretary, School of Agriculture, University of the South Pacific, Alafua Campus Private Mail Bag, Apia, Western Samoa to reach him no later than 28 April 1989. Applicants residing in the UK should also send a copy to the Appointments Office, Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF. (W6033)E

# POST-DOCTORAL FELLOWSHIPS

The Imperial Cancer Research Fund is one of the largest independent cancer research institutes in Europe employing approximately 400 scientists and clinicians. It has a wide-ranging programme in fundamental, applied and clinical cancer research.

There are approximately seventy research groups encompassing the major disciplines of cellular and molecular biology including biochemistry, genetics, immunology, and virology. Most are housed at the main building in Central London; there are also research units at Clare Hall, North London and at Dominion House attached to St Bartholomew's Hospital. ICRF's external clinical units based in major teaching hospitals form the link between fundamental research and clinical activities.

Each research group works independently. All have access to centralized services including cell production, oligonucleotide and peptide synthesis, amino acid and DNA sequencing, a library of DNA probes and somatic cell hybrids for gene mapping, experimental animal breeding and maintenance including transgenic mice, electron microscopy, and a large computer facility.

## Fellowships

Approximately 40 post-doctoral fellowships are available each year to scientists of any nationality. Most of these are three-year fellowships, but visiting fellowships for a period of one or two years are also offered.

Salaries for post-doctoral fellows are in the range of £12,500-£16,000, dependent on age and experience. This is subject to UK tax but avoidance of double taxation agreements exist with all countries of the EEC, the Commonwealth and the USA. Salaries for Visiting Fellows are dependent on age and experience. Visitors are entitled to medical and dental care under the National Health Service. ICRF will provide assistance with relocation expenses.

The projects currently available are listed below.

Applications giving the relevant project number and including a full Curriculum Vitae should be sent by 12 May 1989 to:  
**Recruitment Officer (Ref: 108/R), Imperial Cancer Research Fund, PO Box 123, Lincoln's Inn Fields, London WC2A 3PX.**

1. **John Armstrong**  
Role of ras-like G-proteins in membrane traffic of *S. pombe*.
2. **Lionel Crawford (Cambridge)**  
Transformation of human keratinocytes by human papillomaviruses and oncogenes.
3. **Clive Dickson**  
The function of *int-2* and related growth factors in tumourigenesis and normal fetal development.
4. **Agamemnon Epenetos**  
Design of chimeric anti-tumour immunoconjugates.
5. **Michael Fried**  
Mammalian gene organization and expression.
6. **Michael Fried**  
Molecular analysis and cloning of amplified DNA.
7. **Stephen Goodbourn**  
Regulation of human  $\beta$  interferon expression.
8. **Bridget Hill**  
Drug resistance mechanisms in cells pre-exposed to X-irradiation and expressing atypical multidrug resistance.

## FELLOWSHIPS continued

# UNIVERSITY of GUELPH

## DEPARTMENT OF BIOMEDICAL SCIENCES POST DOCTORAL FELLOW

An exciting opportunity exists for a post-doctoral fellowship to study the role of the hormone relaxin in the regulation of oxytocin secretion by the neurohypophysis. The work will involve *in vitro* techniques to explore the physiological processes involved. It will also contribute to a clinical study of the disease of lactating sows, known as hypogalactia. The work will be carried out in a well equipped laboratory which has other projects on relaxin in progress.

The successful candidate should have completed their doctoral thesis and have experience in tissue culture and organ perfusion techniques as well as in the handling, purification and assay of peptides. A general familiarity with reproductive biology would be an asset, although not essential.

The position will be available from April 1st, 1989. The stipend will be in the range of \$19,000 to \$24,000 and although the initial appointment would be for one year, there would be an opportunity for renewal for a further year given good progress.

Applications should be sent, together with a full curriculum vitae and the names and addresses of three referees, to **Dr. D. G. Porter, Department of Biomedical Sciences, Ontario Veterinary College, University of Guelph, Guelph, Ontario, N1G 2W1, Canada, (Tel. 519-824-4120, Ext. 4900)**, from whom additional information can be obtained.

*The University of Guelph is committed to Employment Equity* (NW3565)E

## POST-DOCTORAL FELLOWSHIPS IN MOLECULAR ONCOLOGY

Up to two positions will be available as early as 6/1/89 in the Department of Therapeutic Radiology at Yale University School of Medicine for young, innovative researchers interested in pursuing problems relevant to the molecular biology, diagnosis, and treatment of cancer. Projects include:

- 1) the development by genetic engineering techniques of new human hemoglobins able to improve delivery of oxygen to hypoxic tumor cells and their subsequent complete genetic, biochemical, and physiological characterization *in vitro* and *in vivo* (e.g., marrow transplant and transgenic mouse model systems), and;
- 2) the study of autocrine and paracrine mechanisms which govern stromal invasion by tumors, activated immune cells, and implanting embryos, with particular emphasis on the molecular biology of lymphohematopoietic cytokines, their receptors, and their biological role in the control of tumor growth, tissue invasion and metastasis, modulation of host response to foreign tumor and embryonic antigens, and alteration of tumor and normal tissue responses to radiation, chemotherapy, and other agents currently employed in cancer treatment.

Preference will be given to candidates with M.D. or Ph.D. degrees and research experience (pre- or post-doctoral) in molecular biology, protein and nucleic acid biochemistry, and/or molecular immunology. Interested individuals should send letters of application, including CV and references, to: **Barry M. Kacinski, M.D., Ph.D. 136 HRT, Dept of Therapeutic Radiology, Yale University School of Medicine, 333 Cedar St., New Haven, CT 06510.** (NW3543)E

## STUDENTSHIPS

## DEPARTMENT OF GEOLOGY 1989 Triton (Europe) PhD Studentship

Applications are invited for a PhD research studentship in Geology to be based at the Department of Geology, University of Wales College of Cardiff and sponsored by Triton (Europe) PLC.

Funding will be over 3 years and at a level comparable to NERC awards but with a premium paid to the student on top of the maintenance grant.

The project will be sedimentary-based and involve regional studies of marine fan deposition. Interpretive Field investigations are planned in Southern France and these will be compared with analyses of seismic and borehole data in other areas.

Applicants who hold, or expect to obtain shortly a good Honours degree in Geology should write as soon as possible to:

**Professor R.B. Kidd, Department of Geology,  
University of Wales College of Cardiff,  
P.O. Box 914, Cardiff, CF1 3YE**

*Curriculum vitae and the names of two academic referees should be supplied.* (8920)F

## St Andrews University Department of Biochemistry and Microbiology POSTGRADUATE STUDENTSHIPS

INSTITUTE OF  
MEDICAL GENETICS**  
(University of Glasgow)

**PhD Studentship**

A studentship leading to the degree of PhD is available from 1st October 1989. The studentship is funded by the Medical Research Council. The project will investigate molecular mechanisms regulating embryonic development in mice. Techniques to be used will include gene-cloning, cell culture, transgenic mice and *in situ* immunohistochemistry and hybridization histochemistry.

Further information may be obtained from **Dr. Rosemary Akhurst, Duncan Guthrie Institute of Medical Genetics, Yorkhill, Glasgow, G3 8SJ**. Tel. 041-339-6996, to whom applications should be made as soon as possible. (8912)F

**MEDICAL RESEARCH COUNCIL**

**National Institute for  
Medical Research**

**RESEARCH STUDENTSHIPS  
FOR OCTOBER 1989**

Applications are invited from students who hold or expect to obtain a first class or upper second degree, and are eligible for the following:

**MRC SCHOLARSHIPS**

**Dr. M. G. Sargent and Dr. P. D. Vize**

Gene products involved in the early stages of embryogenesis of *Xenopus*.

**Dr. F. Grosveld**

Characterization of the DNA binding proteins interacting with the dominant control region (DCR) of the beta-globin gene domain.

**Dr. P. M. Bayley**

The molecular mechanism of Calcium-activated cellular processes.

**Dr. D. R. Trentham**

Real time studies of cellular regulation by the second messenger, inositol trisphosphate (InsP<sub>3</sub>).

**Dr. M. R. Webb**

p21<sup>ras</sup> and cellular signal transduction.

**Dr. D. C. Ogden**

Regulation of ion channels by neurotransmitters.

**Dr. S. A. Wharton**

Receptor binding and membrane fusion interrelationships of influenza virus haemagglutinin.

**Dr. P. W. J. Rigby**

The spatial regulation of transcription during mouse embryogenesis.

**Dr. D. Wilkinson**

Role of zinc finger genes in segmentation in the mouse embryo.

**Dr. R. C. Hughes**

The role of carbohydrates and endogenous lectins in cell recognition.

**MRC COLLABORATIVE AWARDS WITH INDUSTRY**

**Dr. P. C. Emson** (at the Institute of Animal Physiology, Cambridge with **Dr. D. R. Hill** at MSD Research Laboratories, Harlow)

The pharmacology of central CCK expression.

**Dr. A. A. Holder** (with **Dr. D. Snary** of Wellcome Biotech. Beckenham)

Malaria parasite proteins involved in red cell invasion: the structure of a rhoptry protein and its role in inducing immunity.

**Dr. J. F. Eccleston** (with **Dr. P. N. Lowe** of Wellcome Research Laboratories Beckenham)

Structural studies on the interaction of the oncogene product, p21<sup>ras</sup>, with guanine nucleotides and GTPase activating protein.

**Dr. R. W. King** (with **Dr. D. G. Reid** of Smith Kline & French Research Ltd., Welwyn)

Binding of cAMP analogues to cAMP receptor protein.

**MRC AIDS DIRECTED PROGRAMME AWARD**

**Dr. A. J. Hay**

Elucidation of the ion-channel properties of the influenza virus M2 protein — the specific target of the anti-influenza drug, amantadine.

For further details and application form please contact **Dr. R. W. King, Director of Studies, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA**. Tel No 01 959 3666 extension 2279

## Cancer Research Campaign

Fighting cancer on all fronts

### BEATSON INSTITUTE FOR CANCER RESEARCH Research Studentships in Cell Biology

Applications are invited for two Ph.D. Studentships from students expecting to graduate this year in science (first or upper second class honours degree), medicine or veterinary medicine.

Applicants should have a strong interest in cell biology and be prepared to learn techniques of molecular genetics. The projects relate to (1) interaction of retrovirus vectors with haemopoietic stem cells (AIDS directed MRC Studentship) and (2) cell-cell interactions in the control of proliferation and differentiation (CRC Studentship).

Further information may be obtained from Dr I. B. Pragnell (project 1) or Dr J. D. Pitts (project 2). Applicants interested in one or both projects should send a curriculum vitae and the names of two referees to **The Laboratory Manager (Ref. IP/JP), Beatson Institute for Cancer Research, Garscube Estate, Bearsden, Glasgow G61 1BD (041 942 9361) before 15th April.** (8914)F

## ASSISTANTSHIPS

### ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London)

#### DEPARTMENT OF VIROLOGY

### TWO POSTDOCTORAL SCIENTISTS ONE RESEARCH ASSISTANT

required to join expanding team investigating cytomegalovirus infections. Each post is for 3 years.

**POSTDOCTORAL POSITION ONE (ref. PD/RF)** will modulate the cell surface expression of Class I HLA molecules to determine if CMV can use these proteins as cellular receptors. Experience of recombinant DNA or immunological techniques desirable.

**POSTDOCTORAL POSITION TWO (ref. JG/RF)** will study the interaction between CMV and  $\beta_2$ -microglobulin to characterise, sequence, clone and express the viral proteins involved. Experience of the purification of proteins (not necessarily viral) from a complex mixture would be an asset.

**RESEARCH ASSISTANT (ref. SB/RA)** will participate in the studies of CMV,  $\beta_2$ -microglobulin and Class I interactions. Immunological experience desirable. Salary will be paid on Research Scales 1A/1B as appropriate plus £1,650 London Allowance. The Department is situated in modern purpose-built accommodation and is well equipped. These projects will provide ideal opportunities to broaden experience of modern virological techniques. Informal visits are welcome (tel. 01-794-0500 x3210 (Dr. Griffiths), x4118 (Dr. Grundy) or x4201 (Dr. Baldwin)).

Further particulars can be obtained from the **SCHOOL OFFICE (x4262), R.F.H.S.M., Rowland Hill Street, London NW3 2PF**, to which applications (*FOUR* copies of curriculum vitae including the names and addresses of two referees) should be sent by 21 April. (8930)P

### IMPERIAL COLLEGE OF SCIENCE, TECHNOLOGY AND MEDICINE (University of London)

#### Solid State Theory

### Postdoctoral Research Assistantships

Applications are invited for two Postdoctoral Research Assistantships to work with Professor D. Sherrington in the areas of (i) theory of complex disordered systems, including neural networks, and (ii) theory of high temperature superconductors. The posts, which are renewable, will be available from October 1 1989 and will be for one year in the first instance. Salary, which will depend on age and experience, will be on the PDRA A1 scale (currently £11,515 – £17,370 pa, inclusive of London Allowance).

The posts require experience in statistical or many-body physics. Candidates should send their CV and other relevant data to **Professor D. Sherrington, Blackett Laboratory, Imperial College, Prince Consort Road, London SW7 2BZ, UK, to arrive by 20 April 1989.** They should also arrange for two references to be supplied by the same date. (8931)P

### UNIVERSITY OF ST ANDREWS DEPARTMENT OF BIOLOGY AND PRECLINICAL MEDICINE POSTDOCTORAL RESEARCH ASSISTANTSHIP IN COMPARATIVE IMMUNOLOGY

Applications are invited for an SERC-funded postdoctoral research assistantship to investigate non-self recognition and complement activity in protochordates. The post is for two and a half years, commencing in early May or as soon as possible thereafter. Previous experience in biochemistry, immunology or microbiology is preferred. Starting salary will be within range £9,865 to £11,680 per annum, on 1A scale.

Further particulars and application forms can be obtained from the **Director of Personnel Services, The University, College Gate, St Andrews, Fife KY16 9AJ**, to whom applications should be sent to arrive *not later than 28th April 1989.* (8924)P

## SEMINARS & SYMPOSIA

### Update in Cardiopulmonary Research 23–27 October 1989

This five day symposium is organised by the Institute of Child Health, National Heart and Lung Institute, Papworth Hospital, The Royal Postgraduate Medical School and St George's Hospital Medical School. It will deal in depth with all the recent advances in this rapidly moving field.

#### Topics will include:—

- Congenital Malformations of the Heart
- Neural and Endocrine Control of Cardiovascular and Respiratory Systems
- Myocardial Ischaemia
- Pulmonary Circulation
- Heart and Lung Transplantations

#### Speakers will include:—

R H Anderson	T English	T Pexieder
L Allan	N Fagg	J M Polak
K M Allen	T Hallam	K Reimer
N Banner	S G Haworth	M N Sheppard
P Barnes	T Higenbottam	D R Springall
A E Becker	A Hislop	S Steward
G Burnstock	S Y Ho	P Taylor
D Clarke	A Khagani	J Tesh
C Clelland	M L Kirby	R P Thomson
S Cobbe	J Lundberg	J Wallwork
P Cummins	A Maseri	J Warren
F Cuttitta	W Martin	A C G Wenink
J Dark	R Mecham	J Wharton
E Dejana	S Moncada	T Williams
T A Dinh-Xuan	G Moscova	M Yacoub
M J Davies	J Pearson	

#### Venue:—

National Heart and Lung Institute  
Dovehouse Street  
London SW3 6LY

#### Registration fee:—

£200.00 — (or £50.00 for each individual day) includes catering but not accommodation

#### Further details available from:—

Postgraduate Centre  
National Heart and Lung Institute  
Dovehouse Street  
London SW3 6LY

#### Direct telephone line:—

01-351-8172

## AMERICAN ASSOCIATION FOR CANCER RESEARCH

**EIGHTIETH ANNUAL MEETING  
SAN FRANCISCO, CALIFORNIA  
MAY 24-27, 1989**

**Over 2,500 Presentations of Recent Findings  
In All Areas of Cancer Research**

The Association welcomes non-members to its annual meeting. Young investigators are particularly encouraged to take advantage of this opportunity to hear and meet the leading scientists in the cancer field, to participate in workshops on important new laboratory techniques, and to take advantage of the Association's successful Employment Register.

### HIGHLIGHTS OF THE SCIENTIFIC PROGRAM SPECIAL LECTURES

Lawrence A. Loeb on molecular oncology  
Janet D. Rowley on molecular cytogenetics  
Raymond L. White on gene mapping and cloning  
Bert Vogelstein on genetic alterations  
Leonard J. Lerner on antiestrogens  
V. Craig Jordan on tamoxifen therapy

### SESSIONS OF INVITED SPEAKERS

(names of chairpersons in parenthesis)  
Hematopoietic growth factors (*Jerome E. Groopman*)  
Signal transduction and gene expression (*Ronald M. Evans*)  
Molecular and cellular approaches to proliferation and differentiation (*Gary S. Stein*)  
Molecular dosimetry and DNA repair (*Miriam C. Poirier*)  
Targets of anticancer drug action (*Kurt W. Kohn*)  
Immunoconjugates for cancer therapy (*Ralph A. Reisfeld*)  
Prediction of tumor response (*Sydney E. Salmon and Anne W. Hamburger*)  
Molecular aspects of growth regulation of breast cancer by hormones, growth factors, and oncogenes (*Geoffrey L. Greene*)  
New developments in tumors of the urothelial tract (*Alan Yagoda*)  
Novel approaches to drug dosing and scheduling (*Richard L. Schilsky*)  
Prospects for the medical control of the AIDS epidemic (*William A. Haseltine*)  
Epigenetics of cell transformation and tumor development (*Harry Rubin*)  
Role of glutathione S-transferase in drug resistance (*Cecil B. Pickett*)  
Lymphoid receptors and growth factors (*Cox Terhorst*)  
From epidemiology to cancer biology (*Frederick P. Li*)  
Molecular aspects of carcinogenesis (*Arthur P. Grollman*)

### METHODS WORKSHOPS

(names or organizers in parentheses)  
Cloning, expressing, and modifying genes and gene products (*Martin Rosenberg*)  
Transgenic mice as a model for oncogenesis (*Timothy A. Stewart*)  
The polymerase chain reaction: its subtleties and application (*Bernard J. Poiesz*)

### SESSIONS OF SUBMITTED PAPERS

Minisymposia and slide, poster, and poster discussion sessions will be scheduled on all four days of the meeting in all subfields of cancer research

### INFORMATION, REGISTRATION FORMS, AND MEMBERSHIP APPLICATION FORMS

available immediately upon request from:

**American Association for Cancer Research**  
530 Walnut Street, 10th Floor  
Philadelphia, PA 19106  
Telephone: 215-440-9300  
FAX: 215-440-9313

Information also available on the Association's new series of smaller, more focussed scientific meetings: **AACR SPECIAL CONFERENCES IN CANCER RESEARCH** (NW3548)C

## Molecular Communication in Higher Plants

18-21 September 1989  
at EMBL, Heidelberg, F. R. Germany

### Invited speakers include:

D. Baulcombe (GB-Norwich), M. Bennett (GB-Kew), M. Bevan (GB-Cambridge), T. Bisseling (NL-Wageningen), U. Bonas (D-Berlin), C. Bowler (B-Gent), F. de Bruijn (D-Köln), M. Caboche (F-Versailles), N.-H. Chua (USA-New York), A. Clarke (Australia-Melbourne), E. Coen (GB-Norwich), G. Coruzzi (USA-New York), J. Dangl (D-Köln), E. Dennis (Australia-Canberra), A. Gatenby (USA-Wilmington), W. Gerlach (Australia-Canberra), A. Gierl (D-Köln), R. Goldberg (USA-Los Angeles), W. Gruissem (USA-Berkeley), R. Hedrich (D-Göttingen), T. Hohn (CH-Basel), R. Horsch (USA-St. Louis), D. Jofuku (B-Gent), J. Jones (GB-Norwich), J. Leemans (B-Gent), P. Meyer (D-Köln), D. Mohnen (USA-Athens), T. Nelson (USA-New Haven), K. Palme (D-Köln), I. Potrykus (CH-Zürich), P. Quail (USA-Albany), E. Schäfer (D-Freiburg), A. Sievers (D-Bonn), C. Somerville (USA-East Lansing), A. Spina (D-Köln), D. van der Straeten (B-Gent), A. Trewavas (GB-Edinburgh), S. C. de Vries (NL-Wageningen), E. Weiler (D-Bochum), P. Weisbeek (NL-Utrecht), U. Wienand (D-Köln), L. Willmitzer (D-Berlin).

### There will be nine plenary sessions which will cover:

Cell-cell interactions; Differential gene expression/mutational analysis of plant function; Inter and intracellular signalling and the regulation of plant growth; Plant and environment; Plant biotechnology; Plant and microbes; Plants and viruses; Protein traffic and assembly into higher order structures; Structure, modification and expression of the nuclear genome (including novel techniques for gene isolation). The two poster sessions will allow participants to present their work.

### Registration:

The Symposium will be at the European Molecular Biology Laboratory, Heidelberg, with registration on Sunday, 17 September 1989. The registration fee, which includes daily transport to and from the EMBL, lunches, and the Symposium reception, is DM 180, for graduate students DM 90, and for participants from industry DM 360. Participants will be accommodated in the EMBL guest house and hotels in Heidelberg. The registration fee does NOT cover the cost of accommodation.

### Application:

The deadline for applicants is 16 June 1989. Applications should include a curriculum vitae and a brief description of research interests. The organizing committee will notify those who have been accepted as soon as possible after the deadline. The total number of participants will be limited to 250. Applications should be addressed to **Dr. J. Tooze, EMBO, Postfach 1022.40, D-6900 Heidelberg, F. R. Germany**. Applicants wishing to present a poster should send a 1-page abstract together with the registration fee and reply sheet after they have been accepted for participation.

### Organizing committee:

C. Leaver (Edinburgh) -Chairman-, K. Marcker (Aarhus), M. van Montagu (Ghent), I. Potrykus (Zürich), H. Saedler (Köln), F. Salamini (Köln), J. Tooze (EMBO, Heidelberg). (W5907)M

## COURSES & CONFERENCES

### ANNOUNCING AN NIH CONFERENCE

#### Modeling in Biomedical Research: An Assessment of Current and Potential Approaches

#### Applications to Studies in Cardiovascular/ Pulmonary Functions and Diabetes

To be held 1 to 3 May 1989, in Masur Auditorium, The Warren Grant Magnuson Clinical Center, National Institutes of Health, Bethesda, Maryland

Sponsored by the Division of Research Resources, the Division of Research Services, and the Office of Medical Applications of Research of NIH.

Continued innovation and refinement of model systems is crucial to rapid progress in biomedical research. This conference continues NIH's evaluation of modeling, from the use of non-human primates and invertebrate species to cell cultures and mathematical and physical approaches. To emphasize the use of many types of models to solve basic biomedical questions, the conference will focus on two areas of great importance to the nation's health: cardiovascular/pulmonary function (1 May 1989) and diabetes (2 May 1989).

Scheduled presenters on 1 May include: J. I. E. Hoffman, M. Gimbrone and F. Dewey, N. Staub, S. Factor and R. S. Chadwick, C. Peskin, S. Wickline, R. Ruffolo, and K. Brown and R. Robertson. Those on 2 May include: J. Roth, G. Grodsky, O. M. Rosen, D. Greene, A. Rossini, P. Lacy, R. Bergman, and J. Fain.

A panel of scientists chaired by Dr. Gordon H. Sato, Director of W. Alton Jones Cell Science Center, will question the presenters, prepare a summary statement of the material presented, and evaluate the strengths and limitations of the various model systems. On 3 May 1989, the panel will present its draft statement and invite comments from the audience.

To registrar for the conference or obtain further details, contact: **Susan Wallace, Prospect Associates, Suite 500, 1801 Rockville Pike, Rockville, MD 20852; telephone: 301-468-6555.** (NW3544)C

## Royal Postgraduate Medical School

(University of London)

# Monoclonal Antibody Techniques

## SPECIALIST SHORT COURSE

26 – 30th June 1989

Applications are invited for this full-time one week course. The course consists of lectures and practicals covering the following topics:

- ★ Immunisation
- ★ Choice of myeloma lines
- ★ PEG cell fusion
- ★ Electrofusion
- ★ Cloning
- ★ Screening systems
- ★ Antibody purification
- ★ Immuno-blotting
- ★ The effects of affinity/avidity in different assay systems
- ★ Discussion on some of the current uses including antibody engineering and clinical applications

### Course organisers:

M Ritter, H Ladyman, R Hargreaves

### Course fee (incl. catering)

**£300**

### Further details from:

Wolfson Conference Centre,

## EIGHTH CSH CONFERENCE ON CANCER CELLS REGULATION OF EUKARYOTIC mRNA TRANSCRIPTION

September 6 - 10, 1989

Organized by:

Winship Herr, Cold Spring Harbor Laboratory  
Robert Tjian, University of California, Berkeley  
Keith Yamamoto, University of California, San Francisco

The focus of this meeting is motivated by the rapid developments in the field of eukaryotic mRNA transcriptional control. The sessions will focus on:

- Initiation Complexes and Post-Initiation Events
- RNA Polymerase II and Basal Initiation Factors
- Mechanisms of Transcription Regulation: Activation Domains and Protein/Protein Interactions
- Structure and Function of Sequence-Specific DNA Binding Proteins
- The Influence of Template Topology, Nuclear Matrices, and Chromatin Structure on Transcription
- Tissue Selective Enhancer and Promoter Factors
- Regulation of Transcription Factor Activity
- Transcription of Developmentally Regulated Genes.

The meeting will include formal sessions with invited speakers and poster sessions. The organizers invite submission of abstracts. The abstract deadline is **JUNE 28, 1989.**

Kindly forward all forms and correspondence to:

**MEETINGS COORDINATOR  
COLD SPRING HARBOR LABORATORY  
COLD SPRING HARBOR, NY 11724

# INTERNATIONAL CONFERENCE

## "THE GASTROINTESTINAL EPITHELIUM"

September 24-28, 1989,

RIOM, France

This conference is held under the auspices of the Institut National de la Santé et de la Recherche Médicale (INSERM) with the sponsorship of Merck Sharp Dohme-Chibret (France).

**Program:** Cell biology and molecular genetics of differentiation. Differentiation markers. New models for the study of GI epithelial cell differentiation. Maturation, growth and cell renewal. Cell renewal and carcinogenesis. Mechanisms and regulations of transport. Receptors. Interactions between the gastrointestinal epithelial cells and the immune system.

**Organising committee:** K. Haffen, P Hauri, M. Laburthe, M.J.M. Lewin, D. Swallow, G. Willems.

**Invited speakers:** D. Bataille, P. Burtin, J.F. Desjeux, B. Dutrillaux, S. Emami, R. Greig, D. Guy-Grand, D. Louvard, F. Martin, D. Ménard, M. Neutra, B.A.J. Ponder, F. Potet, J. Pouyssegur, J.C. Rambaud, F. Reyl-Desmars, G. Rosselin, G. Sachs, J. Schmitz, P. Simon-Assmann, A. Soumarmon, E. Wright, N.A. Wright, A. Zweibaum.

**Application:** A limited number of places is available for selected participants. Applicants should send a short CV and a brief outline of their research interests with 2 to 3 recent references, **before May 31 1989**, to M.J.M. Lewin (address below). Notification of acceptance will be mailed by June 15.

**Conference fee:** The selected participants will have to pay a registration fee of FF 1,000. Hotel accommodation and expenses will be covered by the Conference.

**Information and Applications to:** M.J.M. Lewin, "The GI Epithelium", INSERM U.10, Hop. Bichat, 75877 PARIS CEDEX 18, France.

Tel. (1) 40.25.83.90 & (1) 40.25.83.93. Fax (1) 46.27.85.36.

Second IIGB Meeting

### Workshop on Molecular Biology of Development

2-4 October 1989, Capri, Italy

Organizers:

Paolo Bazzicalupo, Franco Graziani,  
Edoardo Boncinelli, M. Graziella Persico (IIGB, Naples)

Topics cover:

Gene expression in developing systems as exemplified by  
*D. melanogaster*, *C. elegans*, *X. laevis* and mouse.

Invited speakers include:

M. Ashburner, Cambridge	R. Horvitz, Cambridge, Mass
J.A. Campos-Ortega, Köln	D. Ish-Horowicz, Oxford
M. Chalfie, New York	H. Jaekle, München
T.W. Cline, Princeton	R. Krumlauf, London
I. Dawid, Bethesda	M. Levine, New York
E.M. De Robertis, Los Angeles	A. Martinez-Arias, Cambridge
D. Duboule, Heidelberg	W.J. McGinnis, New Haven
A. Garcia-Bellido, Madrid	D.A. Melton, Cambridge, Mass.
W.J. Gehring, Basel	M. Noll, Basel
P. Gruss, Göttingen	C. Nüsslein-Volhard, Tübingen
J.B. Gurdon, Cambridge	M. Rosbash, Waltham
D. Hirsh, Boulder	A.C. Spradling, Baltimore
J. Hodgkin, Cambridge	C. Wu, Bethesda

The number of participants is limited to 70. Applications, together with a curriculum vitae and a list of research interests, should be sent to Dr. Edoardo Boncinelli, IIGB, Via Marconi 10, 80125 Naples, Italy, before 1st July 1989. A registration fee of US \$ 200 will include board and lodging. Successful applicants will be notified by the end of August 1989.

(W6027)V

First announcement of a workshop on:

# POST-TRANSCRIPTIONAL CONTROL OF GENE EXPRESSION

at the Gesellschaft für Biotechnologische Forschung mbH,  
Braunschweig, West-Germany, April 11 - 16, 1990.

Topics to be covered (in prokaryotic and eukaryotic systems):

1. Control of mRNA stability
2. Roles of antisense RNA
3. Transcriptional (anti-) termination
4. Control/regulation of translation
5. Translational fidelity (including frameshifting)

A list of speakers will be published in the near future. A limited number of places have been left free for further applicants, who should apply to either of the organisers:

Dr. J.E.G. McCarthy  
Gesellschaft für Biotechnologische  
Forschung mbH  
Mascheroder Weg 1  
D-3300 Braunschweig  
West Germany

Dr. M.F. Tuite  
Biological Laboratory

# CUSTOM GENE LIBRARIES IN A FLASH

27 SEP 1989

## With Stratagene's Innovative Vectors And Improved Gigapack™ II Gold Packaging System

Stratagene offers a custom cDNA and genomic library service. Each library is constructed using Gigapack™ II Gold packaging extract (our newest packaging system: mcrA, mcrB, mrr–, hsdR–) and your choice of innovative cloning vectors.

### cDNA Libraries

Send us your poly (A+) enriched mRNA (we recommend the use of Stratagene's RNA isolation kit for isolating total RNA - catalog #200345). We will construct a library containing from  $1 \times 10^6$  to  $1 \times 10^7$  primary recombinant plaques depending on the integrity of the mRNA. Stratagene will also amplify your library at no extra charge. Libraries will be constructed in one of the following lambda phage vectors of your choice: The Lambda Zap®II vector, the Uni-Zap™ XR vector, Lambda gt10, or Lambda gt11 vectors.

### Genomic Libraries

Send us your genomic DNA. Stratagene will perform partial or complete digests and size fractionate the DNA. Stratagene will construct a library containing from  $1 \times 10^6$  to  $1 \times 10^7$  primary recombinant plaques. If desired we will amplify your library at no extra charge. Libraries can be constructed with the Lambda FIX™ II vector, the Lambda DASH™ vector, Lambda EMBL3, EMBL4, or the cosmid vector pWE.

### Pre-Constructed Libraries

Stratagene offers a large selection of pre-constructed libraries. Most are prepared with Stratagene's innovative vectors and are available for immediate delivery. Please call for information on our latest selection. Stratagene guarantees your complete satisfaction.

## **NEPOTISM IN HONEY BEES**

**IMMUNOLOGY/MONOCLONALS**  
product review

Actual scanning electron micrograph of CHO-K1 cells growing on Cultispher-G. Cell density:  $50 \times 10^8$  cells/gm dry weight.

## 2500 Cells. One Microcarrier. CultiSpher-G™

**Cultispher-G.** A new macroporous gelatin microcarrier. Macroporous, so your cells reach tissue-like densities. Better protection from shear forces as cells grow inside. Gelatin means easy to dissolve, so you get higher recoveries. And better preservation of cell architecture. Scale up is easy. Cultispher-G has gone direct from 1 to 40 liters without a problem.

**Cultispher-G.** For more efficient cell culture.

### Technical specifications

Matrix: 100% gelatin  
Density: 1.04 g/ml  
Size:  $d_{50}$  220  $\mu$ m  
 $d_{5-95}$  170-270  $\mu$ m  
Swelling factor: 13-15 ml/g dry weight  
Approx. no. of microcarriers:  $2-3 \cdot 10^6$ /g dry weight  
Thermal stability: Autoclavable

Large internal surface shown by SEM.

### Special Introductory Offer:

For a limited time test Cultispher-G at a special introductory price, 49 USD/10 gms (Ordinary price is 65 USD). Just fill in the coupon. Or fax or write.

**12 high purity  
plasmid preps  
in less than an hour ?**

**Yes, with one of the new  
QIAGEN >plasmid< kits**

**matching CsCl purity**

**with new, short & simple  
rotocols**

**mini, midi or maxi scale.**

QIAGEN Hi purity >plasmid< kits contain our proprietary anion exchange resin QIAGEN in disposable plastic tips, together with all the buffers and solutions required to go from overnight cultures to pure plasmids in 50 minutes (for minipreps, 90 min for maxi preps).

Hi purity kits are available for either 25 Mini- or, 25 Midi or, 10 Maxi preps of DNA of a purity equivalent to CsCl gradients. A fourth kit, QIAScreen, for 300 Mini preps of "screening" quality produces plasmid DNA ideal as a substrate for restriction analysis.

High recoveries  
Excellent reproducibility  
Non-toxic reagents

All you need to get started  
is a

**QIAGEN >plasmid< kit**

# QIAGEN

## the fastest way to pure plasmids

*Mini preparation (plasmid DNA)  
Hi purity ("for sequencing")*

*This protocol is designed for 1-3 ml cultures of E.coli.*

### *Procedure*

- 1. Resuspend the bacterial pellet in 0.3 ml of buffer P1.*
- 2. Add 0.3 ml of buffer P2, incubate at room temp. for 5 min.*
- 3. Add 0.3 ml of buffer P3, centrifuge at 4°C for 15 min.*
- 4. Apply the supernatant to a QIAGEN-tip 20, pre-equilibrated with 1.0 ml of buffer QB.*
- 5. Wash the QIAGEN-tip 20 with 2 x 1.0 ml of buffer QC, and elute the DNA with 0.8 ml of buffer QF.*
- 6. Precipitate the DNA with 0.8 volumes of isopropanol.*

If your research can't wait for weeks while you wait for peptides, take a look at the new Excell™ Automated Peptide Synthesizer from MilliGen/Biosearch.

With the Excell system, you don't have to be an expert to synthesize high-quality, biologically active peptides. Simply enter your sequence, add prepackaged reagents, amino acid cartridges and reaction column, push "Start Synthesis," and walk away.

Using proven Fmoc/BOP + HOBt protocols (no HF), Excell achieves yields > 99% and cycle times < 1 hour.

Excell system Expert™ software recommends the best protocol for your sequence, automatically assigns coupling strategies, calculates reagent amounts, and verifies the sequence. Self-prompting menus guide you through each step, while a real-time synthesis report documents them.

And since it's priced within the reach of most facilities, there's no reason to wait another day. For more information call 800-872-0071; in MA, 617-229-2870.

# Immunocytochemical detection of cell proliferation

The new cell proliferation kit from Amersham –

- A complete kit for the detection of cell proliferation by Bromodeoxyuridine (BrdU) incorporation and monoclonal antibody detection.
- Unique DNase-containing monoclonal antibody allows rapid efficient localization of BrdU-containing cells without the need for harsh chemical pre-treatment<sup>(1,2)</sup>.
- Contains matched and optimized BrdU incorporation reagent, monoclonal antibody and immunoperoxidase detection reagents for bright field microscopy. Detailed protocol booklet.

# nature

13 April 1989

Vol. 338 Issue no. 6216

*Homo sapiens* is not the only species in which nepotism can be demonstrated — honey bee workers prefer to raise queens closely related to themselves. See page 576. Cover photo of a reproductive swarm by N. E. Gary, Department of Entomology, University of California at Davis.

## THIS WEEK

### The main attraction

The large-scale motions in the Universe can be explained by the presence of a 'Great Attractor', with a mass of more than  $5 \times 10^{16}$  times that of the Sun. A survey of galactic redshifts points to a

remarkable concentration of clusters as the origin of the attractive force. Pages 562 and 538.

### Bio-semiconductors?

The peptide-coated cadmium sulphide crystallites produced in some yeasts exposed to cadmium behave as true clusters, with quantum properties such as size-dependent electronic transitions. Page 596. See also page 540.

### Genes in clover

A pea lectin gene expressed in the roots of clover plants allows nodulation by a strain of *Rhizobium* normally specific for pea plants, supporting the idea that lectins may be important determinants of the host specificity of nitrogen-fixing bacteria. Pages 579 and 545.

### Insulin unfolds

The structure of a new crystalline form of hexameric insulin shows how the interaction of proteins with small molecules can affect their folding. Page 594.

### Palaeoclimate

Abrupt changes in the climatic conditions of the North Atlantic during the past 18,000 years may have been caused by the gradual effects of the astronomical forcing regulating the incidence of ice ages, accentuated by the melting of the Laurentide Ice Sheet. Page 553.

### Third GABA subunit

Benzodiazepines regulate GABA receptors, but the two GABA receptor subunits cloned previously do not bind benzodiazepines. A third related subunit has now been cloned that confers a high affinity for benzodiazepines when coexpressed with the other two subunits. Page 582.

### Three-pole fluids

This tripolar pattern (below) has not yet been observed in the

world's oceans, but it is stable in the laboratory, page 569.

### Cell growth factor

Platelet-derived endothelial growth factor has a gene sequence unrelated to that of any characterized protein. Page 557.

### Diabetes risk

A specific allele within the major histocompatibility complex, DQ2, may contribute to susceptibility to insulin-dependent diabetes mellitus. Page 587.

### Guide to Authors

See page 598.

# We specialize in quality, custom peptide synthesis . . . so you don't have to!

Our proprietary techniques enable MPS to supply you with all the custom peptides you need. For example, we can provide over 100 completely different 15-residue peptides in as little as three weeks. An analytical HPLC chromatogram is included with each peptide ordered.

MPS offers quality peptides with service we're sure you'll like. Call us with your questions or if you would like a complete price list.

MPS also provides a custom HF Cleavage Service and a unique HF Cleavage System.

#### COMPARE OUR PRICES

MPS is offering custom peptides at the extraordinary prices listed below.

10mer	\$400
15mer	\$550
20mer	\$800

Prices are based on 50mg of HF Cleaved Peptide. 4 to 6 weeks delivery, minimum order of 3 peptides or \$1000.

#### CAN YOU SYNTHESIZE PEPTIDES FOR LESS?

Before you buy an automated peptide synthesizer, you should consider the actual cost for in-house synthesis which includes the cost of reagents, personnel, service contracts, analysis, waste disposal, downtime and, of course, the initial cost of the synthesizer.

HPLCs of unpurified, HF cleaved peptides

UV-M, the new detector with remote optical unit that provides noise reduction and increased sensitivity

1988

GP-250 PLUS, LCC-500 PLUS and LCC-500 CI, the new series of controllers that store up to 50 methods

1988

FPLC manager, the user-friendly software for system control, data evaluation and reporting

The day we say  
we're perfect,  
don't believe us.

Knowing that every product we make can somehow be improved provides us with a constant challenge. Technology never stands still. Finding better ways to help you manage biomolecules is, therefore, our never ending aim.

FPLC®System serves as a good example. Due to continuous upgrades, it remains the world's leading

1984

Motor Valves MV-7, MV-8, the specially designed valves for easier handling and sophisticated automation

1987-88

Protein A Sepharose and Chelating Sepharose, recent additions to our constantly expanding range of biocompatible columns and media

1987

FRAC-200, the new high-capacity fraction collector

system for fast protein liquid chromatography – the system others use as a reference point. Our series of PLUS controllers store up to 50 methods, for example, and our biocompatible columns and media support every known separation technique. Have you seen the FPLCmanager™ PC software?

Our sights are set on continuing

to lead, not follow, in the development of biomolecular separation tools. To reach that goal, we're committed to listening to what you have to say, understanding your needs and delivering the quality products, service and applications know how that you have come to expect from us.

The 'perfect' system has not been built. But, as FPLC System demon-

strates, we'll never stop looking for better ways to help you manage biomolecules.

Pharmacia LKB Biotechnology

# Get up to 300% more activity from your immobilized antibodies

**New Affi-Gel® Hz immunoaffinity support from Bio-Rad for Fc fragment-specific antibody immobilization.**

**Fig. 1.** Binding of <sup>14</sup>C-BSA to anti-BSA IgG immobilized on Affi-Gel Hz and CNBr Sepharose\* supports.

**Fig. 2.** Binding of <sup>14</sup>C-beta-galactosidase to anti-beta galactosidase IgG immobilized on Affi-Gel Hz and CNBr Sepharose supports.

The comparison shown here between the Bio-Rad method\* and another manufacturer's method clearly demonstrates a dramatic increase in activity with two different antibodies.

## Affi-Gel Hz support advantages:

- Antibody activity is preserved by immobilization through the carbohydrate moiety of the Fc fragment.
- Chemically stable, covalent coupling chemistry
- Increased immobilized antibody activity
- Convenient kit format and bulk quantities available

For further information, contact your local Bio-Rad representative today.

**It's the Chemistry that Counts.™**

# IT IS NOT WORTH TAKING THE SHOT IF YOU ARE UNCERTAIN ABOUT THE QUALITY OF YOUR PEPTIDES.

**Y**ou can waste a lot of time, effort and money on your research if you are not sure about the quality of your peptides. At NEOSYSTEM we feel you should not have to make the choice between price and quality. Thanks to our multi-peptide synthesiser developed in house, we are able

to produce many different peptides simultaneously. This means we can offer high quality peptides at low costs with short delays. Contact us now to discuss your custom peptide requirements.

3 levels you can choose from:

**GOLD** minimum 98 % pure  
900 \* FF/residue

**SILVER** minimum 85 % pure  
650 \* FF/residue

**BRONZE** minimum 60 % pure  
400 \* FF/residue

HPLC profile, amino acid analysis  
sold by net peptide weight 15-20 mg

HPLC profile, amino acid analysis  
sold by net peptide weight 25-50 mg

1 step purification, 200-300 mg

\* all prices +/ - 20% depending on sequence and amount required.

## • Probes and Cloned Genes:

Over 750 human and 40 mouse genomic and cDNA clones are on deposit at the ATCC for distribution to the international scientific community.<sup>2</sup> Included are clones specific to each of the human chromosomes and over 50 probes for VNTR RFLPS. Establishment of the murine collection is just beginning.

## • Human Chromosome-specific Genomic Libraries:

Both EcoRI and HindIII total digest libraries, constructed in Charon 21A from flow-sorted human chromosomes, are available for each chromosome. Partial digest libraries in Charon 35 or Charon 40, insert size range 10-25 kb, are also available for chromosomes 16, 19 and X. These libraries were constructed by the Los Alamos and Lawrence Livermore National Laboratories as part of the National Laboratory Gene Library Project.

<sup>1</sup>Repository supported under contract N01-HD-5-2944 from the National Institutes of Child Health and Human Development and the Division of Research Resources.

<sup>2</sup>Repository Materials are available to qualified investigators for a fee established by the NIH.

## THE PERFECT BIND

*When did Nature  
cover Science in Switzerland?*

*Where are the latest research results about AIDS?*

*What's the latest development in superconductivity?*

Have you noticed that you never manage to lay your hands on that issue of Nature when you need it most!

For a very reasonable cost, why don't you save time and effort by investing in a set of smart and durable Nature binders.

	Single binder	Set of 4	
UK	£5.25	£16.00	Prices include
Rest of World	£7.75	£22.00	postage and packing

Never again will you be at a loss for that vital information. Each binder holds approximately 16 issues and makes sure that key knowledge is kept at your fingertips.

Complete the order form and in no time your copies of Nature can be kept in order

Please send me \_\_\_\_\_ Nature binders Name \_\_\_\_\_

☐ I enclose a cheque for £ \_\_\_\_\_ made payable to Nature Address \_\_\_\_\_

☐ Please charge my credit card for £ \_\_\_\_\_

☐ Visa ☐ AMEX ☐ Access \_\_\_\_\_

☐ Diners Club \_\_\_\_\_

For 117 years, Carl Zeiss has been "The Great Name in Optics". The tradition continues with the best microscope optics ever.

# ALL MICROSCOPISTS DESERVE OPTIMUM PERFORMANCE. ICS OPTICS FROM CARL ZEISS.

ICS optics (Infinity Color-corrected System) are an advanced series of newly-calculated, highly-corrected microscope objectives with infinite image distance. But there is more. ICS optics are integrated into the new series of Zeiss microscopes as fully optimized systems. From the light source to the objectives, eyepieces or camera – everything is in perfect harmony. That is what makes the difference between ICS optics and other optical systems, and what guarantees new levels of image quality and resolution.

## Brighter images with higher resolution.

The Zeiss Plan-Neofluar and Planapochromat ICS objectives provide perfectly sharp images, flat from edge to edge, with incredible color fidelity, brightness, resolution and contrast.

The intermediate image is fully corrected due to the unique objective and tube lens combination patented by Zeiss. This innovation optimizes objectives with infinite image distance and sets Zeiss ICS optics apart from all others. The difference in image quality is real and important to all microscopists.

## Change contrasting methods quickly without compromising image quality.

Contrast-enhancing components are integrated in the new series of Zeiss microscopes without the need for additional image-forming optical components. The result: you can change microscopy

techniques with great ease, from brightfield to darkfield, from phase contrast to polarized light, from DIC to fluorescence, without loss of image quality or resolution or reduction in image size. Consistently superb image quality in all methods: a first in microscopy. The Plan-Neofluar multi-immersion

You'll be surprised at what you can make visible.

objectives even enable you to choose the best immersion medium for brightest fluorescence or optimum contrast.

For every application in light microscopy, in transmitted or reflected light, the new series of Zeiss microscopes with ICS optics will surprise even the most demanding microscopists.

# Is protein chemistry an art or a science?

The art  
of protein  
chemistry is  
the experi-  
mental design.

The science is the  
correct interpretation  
of results. Just as the protein chemist  
integrates art with science, Applied  
Biosystems integrates chemistry and  
instrument design with application ex-  
pertise to become partners with you in  
developing solutions to your problems.

The complexity of the protein  
molecule poses a unique analytical  
challenge. Applied Biosystems' broad  
product portfolio—sequencers,  
synthesizers, amino acid analyzers,

HPLC, high  
performance  
electrophoresis,  
capillary electro-  
phoresis—represents  
a few of the techniques  
needed for structural

elucidation. Leading-edge instrumen-  
tation must be combined with clear  
insight and intuition to be successful.

Breakthroughs in protein  
chemistry derive from intuition and  
systematic analyses. Applied Biosystems  
recognizes this. We invite you, our  
partners in  
research, to share  
your viewpoint.  
Contact us today.

# All in 1

Becton Dickinson Immunocytometry Systems has been the leading edge in Flow Cytometry technology for many years.

A dedicated team of experts is permanently engaged in developing research techniques into new clinical tests for Haematology, Immunology and Pathology.

Becton Dickinson offers completely integrated product packages for cytometry. These include a broad line of Leu monoclonal antibodies and other reagents, FACS brand flow cytometers for advanced research or clinical application, and CAS Quantitative Image Analysis systems. Highly automated data analysis software and controls complete the product line.

Becton Dickinson stays in at the forefront of research and product development and thus in finding total solutions to practical clinical problems. Extending the boundaries of our knowledge. Making them relevant to clinicians, for better patient care.

# The Beckman Answer for DNA Sequencing Automation

As DNA sequencing work increases, so does the need for automation. Beckman's answer? The Biomek® 1000 Automated Laboratory Workstation. Single-handedly it automates the fragmentation steps of the Sanger/Coulson protocol for both fluorescent and radiolabeled sequencing.

## Increase Throughput

With the Biomek, you can process 24 templates in under 45 minutes. That's 36,000 base pairs per day!

## Eliminate Placement Errors

To process 24 templates requires more than 450 pipettings—a tedious, error-prone process. But give the job to Biomek and each step is performed with predictable precision, and no placement errors.

## Pipette Volumes Down to 1.5 $\mu$ L

Essential for your DNA sequencing work, the Biomek performs micro-volume pipetting, handling even viscous solutions with ease.

Call for details! Phone 800/742-2345, or write to Beckman Instruments, Inc., 1050 Page Mill Road, Palo Alto, CA 94304. Offices in major cities worldwide.

# Focus on Accuracy

Knee joint of  
human fetus (H.E. Stain)  
S Plan FL1X NFK2.5X

## ***Olympus autofocus photomicrography takes the error out of focusing***

What the naked eye perceives as sharp and clear often translates into a blurred image on film or paper.

Now Olympus brings you the Vanox-S—the world's first autofocus photomicroscope system—designed to eliminate focusing error in low magnification photomicrography (objectives from 1X to 10X), and ensure needle-sharp imagery throughout the entire magnification range. All you have to do is push the AF button.

And the Vanox-S also enables the use of two 35mm cameras and a large-format camera, incorporated into the body, together with automatic exposure and four photo eyepieces. Light intensity is adjusted with neutral density filters, maintaining color temperature consistency.

The new Vanox-S research photomicroscope system lets you reproduce the actual image you see accurately and with high quality. More easily and consistently than ever before.

VANOX-S

## Your First Choice for Cytokine Research Products

### A history of firsts; a future of firsts.

In 1982, Genzyme introduced the first commercial source of Interleukin-1. Today, we offer the most complete line of products available for cytokine research, and tomorrow, we'll continue to provide you with new products relevant to your new needs.

### Our complete product line includes:

#### Interleukins (IL)

- Interleukin-1 (alpha and beta)
- Interleukin-2
- Interleukin-3
- Interleukin-4
- Interleukin-5
- Interleukin-6
- Antibodies to Interleukins
- InterTest-2,™ IL-2 ELISA kit

#### Colony Stimulating Factors (CSF)

- Granulocyte-Macrophage CSF
- Granulocyte CSF
- Macrophage CSF
- Antibodies to CSFs
- Factor-Test,™ GM-CSF ELISA Kit

#### Tumor Necrosis Factor (TNF)

- Ultrapure TNF-alpha
- Recombinant TNF-alpha
- Antibodies for Neutralizing TNF-alpha and TNF-beta (lymphotoxin)
- Antibodies for Western Blot Analysis of TNF-alpha
- TNF-Test,™ TNF-alpha RIA kit

#### Platelet-derived Growth Factor (PDGF)

- Recombinant Human PDGF
- Antibodies to PDGF

#### Additional Products for Immunology Research

- Interferon-gamma
- Antibodies to Interferon-gamma
- Antibody to Erythropoietin
- Recombinant Ultrapure Protein-A
- Recombinant Protein-A Agarose
- Chicken Collagen II

### Our commitment to you.

Genzyme is committed to providing the research community with the highest quality products available. All of our products are subjected to rigorous quality control testing for purity, bioactivity, cross-reactivity, sterility and endotoxin.

In addition, Genzyme's scientific staff is ready to assist you with technical product support.

### Order today for delivery tomorrow!

Our Cytokine products are available as both recombinant and natural preparations and are of human or murine origin. Genzyme also supplies monoclonal and polyclonal antibodies and complete immunoassay kits. For more information or to place an order for next day delivery, call or write today.

## THE NEW SEROTEC MOUSE MONOCLONAL ISOTYPING KIT

# One step.

# One hour.

## Once again Serotec add to the range of affordable excellence

Why waste time with lengthy ELISA and IMMUNODIFFUSION procedures? With the NEW Serotec Mouse Monoclonal Isotyping Kit you can have conclusive results to the class/subclass of your monoclonal antibody in **ONLY 1 HOUR** (and there are no inconvenient washes or incubations).

The kit is ideal for • characterising class/subclass of monoclonal antibodies • detecting mixed clones • isolating class-switch variants • monitoring clones for loss of ability to secrete antibody • screening for specific isotypes

during cloning and selection of novel antibodies.

To place an order or to obtain more information contact:

**Note – Kits for rat and human subclasses to follow soon!**

## How often do we fly to Switzerland?

As you might imagine, Swissair flies to Switzerland with unfailing regularity.

With a wide choice of flights to Basle, Geneva and Zurich from Heathrow, as well as direct flights from Birmingham and Manchester.

Together with award-winning food, drink and a standard of in-flight service you can set your watch by.

We believe that when it comes to business travel to Switzerland, it's not just quantity, but quality that counts.

# ALKALINE PHOSPHATASE

# 6000<sub>U/mg</sub>

Over the past seventeen years, Biozyme has developed the isolation of highly purified enzymes for diagnostic, pharmaceutical and immunochemical application.

The latest development is Alkaline Phosphatase (from Calf Intestine), Code ALPI-11G assaying at 6000 U/mg protein (Biuret) or greater (Diethanolamine buffer, 37°C). Offered as a 50% glycerol solution, this presentation has a stability of at least 18 months at 0-5°C.

**The highest  
specific activity  
available**

We list below the range of Alkaline Phosphatase prepared in our laboratories with relative activities in three assay systems, as follows:-

Product Code	Glycine Buffer pH9.6 25 C Biozyme Assay U/mg	Glycine Buffer pH10.4 37 C U/mg	Diethanolamine Buffer pH9.8 37 C U/mg
ALPI-8G	~1100	~1400	~3000
ALPI-9G	~1300	~1700	~4300
ALPI-10G	~1500	~2100	~5000
ALPI-11G	~1700	~2300	~6000

**PROMAB™**  
**PROSEPT™**  
**PROTEIN-A**

**• ALL YOU NEED**

A complete kit for purification of antibodies, containing a unique 1ml Prosept™-A reusable cartridge with luer fittings, specially formulated buffers and detailed protocols.

**• HIGH CAPACITY**

Twice the capacity of other reagents without the use of high salt buffers.

**• IgG1? - NO PROBLEM**

Purify IgG1 subclasses with ease, without high salt to denature the antibody - up to 10 times recovery compared with other reagents.

**• PURIFY DIRECT FROM CULTURE SUPERNATANTS**

The unique properties of the Promab™ cartridge mean you can purify antibodies direct from culture with high recoveries.

**• FAST!**

Using syringes for loading, washing and elution means antibodies can be purified in minutes.

**Prosept™-A** is the exciting new Protein-A reagent at the heart of the **Promab™** kit. Protein-A is immobilised onto controlled pore glass beads using a proprietary chemistry, which produces a rigid, stable, high capacity reagent with unique Ig binding properties and very rapid binding and elution kinetics for fast separations. Prosept™-A is available separately from Porton in 5ml and 10ml packs.

## DIRECT PROTEIN TRANSFER INTO CELLS & OOCYTES

**Q: What is this?**

**A:** This is a new technique to **directly, simultaneously, reproducibly, and rapidly** transfer protein molecules into **many** cells and oocytes by **BAEKON Transfer System**.

**Q: What kinds of protein have you tried to transfer with this technique and what are their molecular weights?**

**A:** So far, we have tried many proteins including antibodies, structural proteins, regulatory factors, and enzymes. Their MW ranges from 20-160 kD.

**Q: Are the proteins active/functional inside the recipient cells?**

**A:** Yes, they are fully functional. For structural proteins, they can be assimilated as cellular components; for enzymes, they retain enzymatic activities; for antibodies, they inhibit respective cellular processes.

**Q: What are the recipient cells?**

**A:** Culture cell lines, e.g., 3T3, PC-12; primary culture; human, mouse, *Xenopus*, and *Drosophila* oocytes.

**Q: What percentage of the cells get transferred?**

**A:** Greater than 95%.

**Q: Are the recipient cells viable?**

**A:** Yes, viability is greater than 95%.

**Q: Can post-transferred oocytes and embryos develop normally?**

**A:** Yes.

**Q: What can I do with this technique?**

**A:** A lot: to study the function and localization of a gene product, and to regulate gene expression by transferring specific gene products, regulatory factors, enzymes, or antibodies into cells. **Imagine...!**

**Q: What instrument have you been using for the transfer experiments?**

**A: BAEKON 2000\*:** If you want to know more about this instrument and the whole scope of application, protocols, as well as experimental details, please contact **BAEKON**.

**BAEKON, INC.**  
 18866 Allendale Ave.,

\*This instrument has successfully been used to transfer genes into mammalian cells (T- & B-lymphocytes, hepatocytes, fibroblasts, kidney & neural cells, etc.), plant cells (monocot & dicot, both intact cells and protoplasts) and bacterial cells (Gram positive & negative). It also has been used to induce cell fusion among mammalian, fish, plant, and bacterial cells.

## Proven tolerance

Prof. Griscelli — Prof. Akoun — Prof. Paupe — Dossier of A.M.M.)

form and presentation. Coated tablets (white) in blister packing, box of eight. Ingredients. Weight of ingredients 1 mg. Weight of box 8 mg. Glycoproteins extracted from *Beauveria pseudocillata* retained on a membrane of average porosity 0.011 micrometres and expressed in anhydrous product. Excipient: lactose, corn starch, glycidol, magnesium stearate, cellulose, croscarmellose, sodium carboxymethylcellulose, colloidal silicon, talcum, polysorbate 80, titanium dioxide, circelanche q. s. p. per 400mg tablet. Properties. (cp. monograph by Vidal). BioSTIM is an immunostimulant. Tests have shown it to reactivate all three levels of

defense against infection (phagocytosis, humoral reactions, reaction to cellular medication). BIOSTIM, by reactivating the immune system, has been shown in tests to protect against bacterial or viral infection whether it be intra or extra-cellular in development. This action has been demonstrated in both the normal and the immuno-depressed animal. The effectiveness of annual treatment by BIOSTIM has been established, through controlled double blind tests against a placebo. Used for preventing chronic infections of the respiratory organs, BIOSTIM ensures: a reduction of the risk of subsequent reinfection, a shortening of attacks of bronchial infection. Directions.

## Genuinely effective (proved by DB/placebo)

Prophylaxis of recurring infections in both the adult and the child

The unique ultra-small immunogold probe for  
increased labelling efficiency and penetration power

# AuroProbe One TRADEMARK

## WHY USE AN ULTRA-SMALL GOLD PROBE IN YOUR RESEARCH?

Janssen research developed the **AuroProbe One** technology around colloidal gold particles approximating 1 nm\*.

AuroProbe One penetrates tissues and binds to target antigens with higher efficiency than conventional, larger immunogold probes. That penetration power and labelling density improves

immunodetection, whether you are immunostaining tissue or probing for antigen on blots. The **IntenSE\*\*** silver enhancer, required for visualization, uses the relatively larger number of gold nuclei to yield a stronger signal. Signal-to-noise ratios are markedly improved, and endogenous tissue reactions are absent. You won't

← *In situ* hybridization of cytomegalovirus (CMV)-infected adrenal gland using biotinylated entire CMV genome, rabbit anti-biotin, AuroProbe One and IntenSE.  
(Volkers, van den Brink & Houthoff, Amsterdam)

Cryosectioned synaptosomes reacted with rabbit anti-B50, AuroProbe One and IntenSE.  
(van Lookeren-Campagne & van Bergen en Henegouwen, Utrecht)

← Blot of total extract of Hela cells and blot of partially purified nuclei of rat liver reacted respectively with rabbit anti-tubulin (a) and rabbit anti-actin (c) followed by AuroProbe One and IntenSE. Negative controls (b, d)

PK<sub>2</sub> cells reacted with rabbit anti-tubulin, AuroProbe One and IntenSE

For research use only

need separate AuroProbe One reagents for microscopy and blotting applications as the ultra-small gold probe is an all-round marker system.

**Order now! Witness the power and efficiency of AuroProbe One for your research.**

## NEW PREM<sup>TM</sup> II – Programmable Restriction Enzyme Module

When the heat is on  
PREM<sup>TM</sup> keeps its cool

### Fast reliable heat sequencing

When you need sufficient quantities of DNA or other biologically significant molecules for your research, the PREM<sup>TM</sup> II takes the heat out of the situation – FAST. For example, 95°C to 40°C in one minute or less – and back again, equally FAST.

PREM<sup>TM</sup> is a reliable heat sequencing device which gives you the precise control of temperature conditions you need for gene amplification, to save you time and give you total flexibility.

### DNA Applications

DNA Applications include restriction enzyme digestion, preparative work for DNA sequencing, polymerase primer extension and numerous biochemical reactions where precise temperature and time are essential.

- Fast, reproducible and flexible
- Heat/Cool temperature transition close to 1°C/sec on average
- Total software flexibility
- Minimum of 20 user definable programmes
- Capacity for forty-one 0.5 ml micro-centrifuge tubes
- Entirely solid state for better temperature control and faster temperature cycling

## Gorbachev needs an answer

Mr Mikhail Gorbachev's visit to London last week has sharpened still further the issue of NATO's tactical nuclear weapons. NATO cannot pretend that the issue is technical and exclusively its own concern.

LAST year's tragic earthquake in Armenia has cast a long shadow. That is the simplest explanation why Mr Mikhail Gorbachev's visit to London last week was probably as much a disappointment for him as for many of those who heard what he had to say. His original plan had been to follow his speech at the United Nations in December, when he made public his plan unilaterally to cull 500,000 people from the Soviet armed services, by travelling to Cuba and then to London. Then, in the interregnum between the Reagan and Bush administrations in Washington, it would have been easier for him to open a fruitful dialogue on arms control. By last week, the momentum had been dissipated. Worse, the British government, now preoccupied with the sharpening dispute within the North Atlantic Treaty Organization (NATO) about the continuing role of nuclear weapons in Europe, was in no mood to respond imaginatively.

The issue is simple, but none the less corrosive on that account. The treaty on missiles of intermediate range (INF) signed at the end of 1987 regulates the removal from Europe of missiles capable of carrying nuclear warheads a distance of 1,500 km or more, but only implicitly regulates missiles of shorter range. (A precondition of INF was the readiness of NATO and the Warsaw Pact to remove tactical nuclear weapons from the scene.) Now, NATO wishes to improve ("modernize") the performance of its tactical nuclear weapons over the next few years. Specifically, there is a plan for replacing the Lance missiles now sited in West Germany with improved rockets capable of travelling 500 km. The Soviet Union disapproves — Gorbachev said so plainly last Friday. So, for different reasons, does West Germany.

Gorbachev's view is that improving the performance of NATO's tactical weapons will break the spirit if not the letter of INF. He said last week that if NATO goes ahead with its planned modernization, the talks on the regulation of conventional arms now under way in Vienna will be jeopardized. NATO's counter-argument is that nuclear weapons remain a necessary part of the defence of Western Europe. At least so long as the intended agreement on conventional forces in Europe remains in the future, nuclear weapons may be the only way of halting an armed incursion. That view is not new: NATO has held to the same doctrine for a quarter of a century. The novelty is twofold — there is now a chance of winning an agreement on conventional forces, while West German voters

and thus, perforce, the West German government are increasingly attracted by the even brighter prospect of a more general disappearance of political and military tension in Europe.

Formally, so far as NATO is concerned, the issue is intended to be settled in the summer of this year, after the Bush administration's review of its security interests (and the associated defence budget) is complete. But that is more than NATO's managers can reasonably expect. If anything, the reluctance of West German voters to support governments which agree to give house-room to modernized weapons is more likely to grow than to melt away. A further difficulty is that the Vienna negotiations will not make sense if aircraft and other remote means of delivering bombs (nuclear or otherwise) are excluded, which is what NATO asks.

That is why the need now is for a constructive compromise. Gorbachev's protest that NATO's insistence on improved nuclear weapons in Europe would jeopardize the Vienna negotiations was quickly countered, in London and Washington, by a simple reiteration of the need to modernize outdated nuclear weapons. Why not, instead, acknowledge that the need for battlefield nuclear weapons in Europe would be diminished if the Vienna talks succeed, and thus make the planned changes contingent on failure at Vienna? That way, Gorbachev and his counterparts in the West could be saying much the same thing, while the important negotiation at Vienna would be invested with a sense of urgency. □

## Disorderly publication

There is no reason why discoveries should not first be published in daily newspapers, but there are drawbacks.

THE great fuss about cold fusion over the past few weeks raises important questions about the scientific literature and its function to which the scientific community should give urgent thought. Reports that nuclear fusion had been brought about in an electrochemical cell first appeared in two financial newspapers — the *Wall Street Journal* and the *Financial Times* — on 23 March. Professors Martin Fleischmann (Southampton) and Stanley Pons (Utah) were reported to have accomplished fusion in an electrolytic cell.

Soon it also became known that a group at Brigham

Young University led by Professor Steven E. Jones was ready with comparable but not identical observations. The University of Utah promptly held a press conference at which, among other things, an article by Fleischmann and Pons was said to have been submitted to *Nature*. In the event, the first article to arrive was from the Brigham Young group, but one from Fleischmann and Pons reached us later; an extended version of it was published last week under the heading "preliminary note" in the *Journal of Electroanalytical Chemistry* (see page 537).

It is no disrespect to any of those concerned to compare the dilemma created for *Nature* by these events to that occasioned a year ago by the article in which Professor Jacques Benveniste and colleagues claimed that indefinitely diluted reagents retain their biological effectiveness. The claim flies in the face of orthodox belief, but the data available are insufficient for a careful judgement of its validity. But on this occasion, *Nature* has followed standard procedures. Both articles have been sent to referees, each is now being revised in the light of the many comments that have been made. Many of these would normally require extensive reinvestigation. In the normal course of events, weeks or months might go by. Researchers are used to delays of that kind, especially when they have important things to say. The process is beneficial because it improves the quality and reliability of what is published.

What is to happen now? Public and professional curiosity now require rapid publication, but there is only a small chance that either group of authors can make all the amendments asked of them in a short time. So should publication be postponed until they can do so? There is a sense in which that would not matter: the information is already in circulation. But publication is more than merely the circulation of information to those with access to the appropriate networks. General availability is crucial. That is why revised versions of one or other or of both articles will be published later in the month. In these exceptional circumstances, they will be accompanied by such comments of the referees as remain pertinent.

None of this implies that the peer-review system is infallible. Those who live with it know that it is shot through with imperfections. There is, for example, a danger that it induces too much uniformity in the literature. But the system is a powerful means by which good ideas are made better on their way into print. The practical question for the scientific community, and for journals in particular, is to adapt the system (and the process of publication) more swiftly to the steady improvement of communications.

Nobody can sensibly complain about those developments. But there remains an immense difference between the discussions thus stimulated within the scientific community and the broadcasting of claims not fully tested. Fleischmann and Pons said at their press conference that their work was in danger of "leaking out", much as Benveniste last year cited reports in *Le Monde* as a cause for urgency. But the authors of an experiment are best

placed to determine when and how news of their work is published generally. It is naturally difficult to bottle up exciting news, but impatience is a poor guide to action. The greater the importance of a discovery seems, the longer it should be worthwhile waiting to see it properly established. □

## Pan-European university?

The Swiss are nursing the idea of creating a European university and should be encouraged.

PLANS to turn the European Economic Community (EEC) into a genuine common market at the end of 1992 may not yet have done much to change economic behaviour in the 12 countries directly involved, but they have had a powerful influence on outsiders. Japanese and US companies are busy building factories in member states or forming business partnerships with companies registered there. Governments are similarly impelled by a sense of exclusion to seek membership of the EEC: Turkey has formally applied, Austria says it will and Norway (for the second time) is brooding. The way things are going, by 1992 there may be only one European outsider left outside — Switzerland.

This prospect keeps stoical Swiss awake at nights. Their difficulty is plain: the constitution of the Swiss Federation, with its devolution of power from the centre, could not be changed without changing Switzerland. Yet it was already plain last year (see *Nature* 336, 323 *et seq.*; 1988) that anxiety about the emerging single market had become an influence in Swiss planning of research as well as a source of fear that Switzerland may become an amalgam of holiday resort and retirement home for nationals who choose to spend their working lives elsewhere. But anxiety is a catalyst of the imagination, whence the notion now gaining ground that Switzerland, within the confines of its constitution, might make a distinctive contribution to the development of Europe by creating a university on a grand European scale.

This is a daring notion, but none the worse for that. Europe, taken as a whole, has a commendable diversity of universities, but most of them are bound to seem parochial by the yardsticks of the pan-Europeans. But Switzerland has a cosmopolitan tradition rivalled only by that of the Netherlands and might — so the calculation goes — be able to build from its existing institutions a distinctively European university that can be counted among the half dozen or so outstanding universities in the world. For the time being, of course, this is just a dream, but one which many influential Swiss are eager to explore. Altruism is not the only driving-force, of course: to be the site of an acknowledged leader among European universities would be an assurance against isolation, while a strong research programme would undoubtedly engender spin-off. But it is a notion that universities elsewhere in Europe should be ready to welcome. □

# Prospect of achieving cold fusion tantalizes

- Confirmation reports trickle in
- Dispute over primacy

## Washington

SCIENCE by press conference continued this week as Texas A & M University at College Station announced on Monday that researchers there had replicated at least one feature of experiments purporting to show nuclear fusion at room temperature. By the afternoon, a similar announcement had been put out by the press office at the Georgia Institute of Technology, Atlanta.

The Texas group, led by Charles Martin, is getting between 60 and 80 per cent more energy out of its experimental apparatus than it is putting in.

The Georgia group, led by Dr James Mahaffey, has measured neutrons from a palladium cell, recording a fifteenfold increase above background when current was flowing through the cell.

University of Utah chemist Stanley Pons, who first described the cold-fusion experiments at a press conference on 23 March, has confidently predicted that several groups would confirm his experiments. Other groups in the United States, working from preprints of a paper by Pons and Martin Fleischmann that has now appeared in the 10 March issue of the *Journal of Electroanalytical Chemistry and Interfacial Electrochemistry* (261, No. 2a, 301-308; 1989), have not reported either the excess heat production or the appearance of 2.5 MeV neutrons.

Meanwhile, a legal battle is shaping up between the University of Utah and Brigham Young University (BYU) over who first discovered the cold-fusion process. The University of Utah filed a patent application during the week of 13 March, but officials at BYU believe that research done by faculty member Robert Jones along similar lines clearly precedes the work done by Pons. BYU will file a patent application shortly.

Paul Richards, director of public communications at BYU, says his institution felt no pressing need to obtain a patent, as applications for the technology were likely to be far in the future, and the results were of more scientific than commercial interest. Richards adds that BYU felt compelled to file a patent claim in response to accusations that Jones had stolen Pons's ideas.

The relationship between the BYU and University of Utah research teams has been rocky for some time. Last September, Jones was asked to review a grant application submitted to the Department of Energy (DoE) describing the Utah

team's efforts in cold fusion. The grant was ultimately approved. But as well as submitting his comments on the grant to DoE, Jones asked that DoE contact Pons and suggest a collaboration using a neutron detector Jones had developed. DoE did so, but efforts to bring the two groups together were unsuccessful. Ultimately the relationship between the two teams deteriorated to the point where the presidents of both universities met with the leaders of the two research teams to try to clear the air.

That meeting took place on 6 March. Both groups agreed to meet on 24 March at Salt Lake City airport to send simultaneous express packages to *Nature* containing their research results. The timing was crucial, as Jones had agreed to speak at a meeting of the American Physical Society in early May, and they were anxious to have a paper accepted by a peer-reviewed journal before then. Jones cancelled a seminar on his work that had been arranged for 11 March.

But in the intervening weeks, the University of Utah did two things that BYU considered in violation of the agreements worked out on 6 March. On 11 March, Pons and Fleischmann submitted a paper containing details of their cold-fusion experiments to the *Journal of Electroanalytical Chemistry and Interfacial Electrochemistry*, and on 23 March held a press conference to describe their findings. The BYU team was particularly annoyed when, during the press conference, University of Utah vice president for research, James Brophy, told reporters he was unaware of any other groups doing similar work.

The BYU group decided there was no longer any reason to delay, and sent its paper to *Nature* on 23 March. That at the University of Utah sent its on 24 March.

Brophy says the press conference was scheduled after the university learned that a local reporter was planning to publish a news item describing the findings. But Pons says the press conference was held because the paper had already been accepted by the *Journal of Electroanalytical Chemistry and Interfacial Electrochemistry*, although a news release from the journal's publisher, Elsevier Sequoia, states that the paper was accepted on 30 March.

Meanwhile, in Utah, the state legislature has set aside \$5 million to support fusion research once a state commission to be appointed by the governor is convinced that the findings have been confirmed. □

## SOVIET SUBMARINES

### Pollution fears for Norwegian Sea

#### London

A Soviet nuclear submarine of experimental design sank last week, with the loss of 42 lives, in international waters in the Norwegian Sea, between Bear Island and the Norwegian coast.

The immediate reaction in Norway has been one of consternation, even though Dr Willy Ostreng of the Fridtjof Nansen Institute (which studies security issues in northern waters) says that it "was only a matter of time" before such an accident happened in one of the world's most "heavily submarine-infested" channels.

Surface water and air samples collected by the Norwegian authorities have so far shown no signs of radioactive contamination. A Norwegian team is expected to reach the area on Thursday this week, with the intention of collecting deep-water samples, when it is hoped that a preliminary estimate of the immediate danger of contamination will be possible.

The submarine was equipped with two reactors, each of them cooled by a molten mix of lead and bismuth. If the fire which appears to have been the immediate cause of the disaster did not damage the integrity of the reactor compartments, and if the reactors were shut down before the ship sank, there is at least a chance that radioactive fuel elements will be entombed in a now-solid mass of metal from which radioactive material will be released only slowly.

As after the Chernobyl accident, the incident has become something of a test of *glasnost*. The Soviet side has released a certain amount of information, but *Pravda* complained at the weekend that Western journalists were able to get more information from Soviet embassies abroad than its own correspondents were able to gather in Moscow. Even so, the Norwegians are still clamouring for technical details so as to be able to calculate the long-term risk.

Vera Rich

## SOVIET UNION

### Reforms begin to take effect

#### London

THE Soviet Union announced last week that, under its new mental health legislation, more than 60,000 people have been taken off the registers of psychiatric clinics during the past year in Moscow alone. Eventually, it is expected that some 1.2 million Soviet citizens will be removed from the registers. How many names will remain on the registers is unclear. But the new legislation stresses that no citizen may now be hospitalized without his or her consent, except for people "posing an immediate threat to society".

Vera Rich

## Culprit found at Cornell

### Washington

BLAME for a computer 'worm' that crippled thousands of installations on the Internet computer network last November has been placed squarely on the shoulders of Robert Tappan Morris by a commission of inquiry at Cornell University, where Morris is a graduate student.

The attack raised many questions about the security of computer networks to unwarranted entry. But according to the Cornell inquiry, made public late last month, Morris's actions did not so much represent "an heroic event that pointed up the weaknesses of operating systems" as "a juvenile act that ignored the clear potential consequences".

The worm was released on 3 November, 1989 and infected computers using particular versions of the UNIX operating system (see *Nature* 336, 97; 1988). Although it was first diagnosed as a computer 'virus', the infecting program is more properly known as a worm, as it does not require another computer program to act as a 'host' to carry it from one machine

to another.

According to the inquiry's findings, the worm consisted of two parts; a 99-line 'probe' written in the 'C' programming language, and a much larger 'corpus' that had been compiled into machine language. If the probe was able to get into a computer, it sent for its larger body. The probe used four basic methods to gain entry. Two used specific design features of UNIX mail programs that allowed the worm to enter a new machine without passwords that would normally be required. Another avenue was essentially a sophisticated guessing game in which the worm exploited a human tendency to choose simple passwords related to account names. A fourth method exploited a design feature of UNIX that allows people to use the same password on several different machines where they have accounts.

After releasing the worm on the evening of 3 November, Morris evidently decided he had made a mistake, and asked an associate at Harvard to send a message to computer users around the country telling them how to protect themselves against the worm. But the warning was sent by a slow method, and arrived after others had discovered the worm and developed ways to defeat it.

The commission concluded that several thousand computers were infected by the worm, but thousands more had to be shut down as a precaution to prove that infection had not occurred.

The commission points out that Morris was able to exploit security flaws in the UNIX operating system but that UNIX was never designed to be a secure system and many of the flaws were already well known. The commission concluded that creating the worm required "dedication and perseverance rather than technical brilliance", adding that Morris "displayed naive conceit in assuming that he could launch an untested, unsimulated, complex worm onto a complex network and have it work correctly the first time".

Morris declined to be interviewed by the commission of inquiry on the advice of his counsel, but from talking with his colleagues and friends and by examining logs of Morris's computer activities, the commission concluded that Morris alone had written the worm.

Although the commission recommends strong disciplinary action, it suggests that the discipline "should not be so stern as to damage permanently the perpetrator's career". Cornell University has not yet decided on any punishment for Morris. An investigation of the incident by the Federal Bureau of Investigation has not yet resulted in any indictments.

Joseph Palca

## Britain to expand?

### London

BRITAIN has played only a minor role in Arctic research until now, with total funds from the research councils of little more than £1.5 million last year. The Natural Environmental Research Council (NERC) now wants to change this, so that Britain can act at least as a useful partner in international research programmes.

Last year, NERC spent less than £500,000 on Arctic research, mostly on individual research grants and training awards; there are no institutional research programmes devoted to the Arctic. NERC has now asked for an additional £2 million a year from next year's science budget for Arctic research.

The council has rejected the suggestion that it create an Arctic research institution with permanent research bases comparable in size to those in the Antarctic. "On political and financial grounds", this would be unrealistic, it says in its first strategy document for the Arctic, published this week. Less ambitiously, it wants to build a small base on Svalbard, the archipelago north of Norway. The base would be intended to house about 20 researchers and to cost only £70,000 to build and £50,000 a year to run.

The council also wants to increase support for the Scott Polar Research Institute at the University of Cambridge. With more staff and increased and secure long-term funds, this institute would become the focus of British Arctic research, says Dr John Bowman, secretary of the council. But he stresses that expansion here will not compromise research elsewhere in the country. Research areas to which the council gives priority are meteorology, solar-terrestrial physics, oceanography, glaciology, ecology, geology, socio-economic sciences and engineering.

Christine McGour

## Explorers selected

### Washington

The National Aeronautics and Space Administration (NASA) last week announced the first four in a series of small scientific missions that will be launched on existing expendable launch vehicles. The small scale missions — with total costs for each spacecraft expected to average \$30 million — are intended to provide research opportunities for a new generation of space scientists and engineers.

The four projects, chosen out of 51 applications, include the Solar, Anomalous and Magnetospheric Particle Explorer, the Submillimeter Wave Astronomy Satellite, the Fast Auroral Snapshot Explorer and a global ozone satellite that will carry a total ozone mapping spectrometer.

## Pakistani virus invades Indian neighbour

### New Delhi

'C-BRAN', a computer virus of Pakistani origin, has hit personal computers throughout India in what is thought to be the first epidemic of its kind in the nation. The incident highlights India's extensive trade in pirated software and copied floppy disks.

In just four weeks, 'C-bran' showed up in computer schools and a private company in Bangalore and in some 20 companies in Bombay, including an international bank. The virus was also reported from Madras, Kanpur and Vijayawada, a small town where 750 of 1,000 floppy disks used by a private company were found to be infected. Scientists at the Delhi University Computer Centre said their machines were invaded by the 'ashar' variant of the virus.

Dr N. C. Kalra of the Indian Institute of Technology in Delhi, who detected 'ashar' in the institute's computer, centre blamed the epidemic on pirated software. No virus has yet shown up in computers linked by electronic networks but government agencies have been alerted. India's NICNET links the Cybercomputer main-frame computer in the Planning Commission with portable computers in district headquarters while another network, ERNET links the computer centres of eight educational institutions. The six major commercial computer networks all claim to have strengthened their security system following the epidemic. K.S. Jayaraman

## RAIN FORESTS

# Disputes about destruction

## São Paulo

By quoting figures that downplay the extent of Amazon deforestation, Brazil's President José Sarney last week touched off a dispute over estimates of rain-forest destruction and embarrassed his nation's own Instituto de Pesquisas Espaciais (INPE, Institute of Space Research).

Sarney's comments came as he signed into law legislation that creates the 'Nossa Natureza' (Our Nature) programme designed to protect the Amazon forests (see *Nature* 338, 286; 23 March 1989).

He harshly attacked 'foreign intervention' in Brazil's Amazon policy and, to prove that the destruction of Amazon rain forest is not as bad as foreigners claim, he noted that the latest data on deforestation calculated by INPE scientists show that just 5.12 per cent of the rain forest has been cleared since the colonization of Brazil began in 1500.

But that figure is in dispute. A 'green' federal deputy, social-democrat Fábio Feldmann from São Paulo, claimed the data had been 'manipulated' to suit government needs. The '5.12 per cent' derives from figures on the destruction of tropical moist forest. But the INPE team responsible for the analysis related the area destroyed (250,429 square kilometres) to the total area of the Brazilian Amazon region,

rather than to the total area of rain forest, which is smaller (see map).

Barbosa said the team did not relate deforestation data to total rain-forest area because "we do not know the true extent of the rain forest". But other INPE researchers said they thought it was a mistake to present the data that way. To pre-

The Brazilian Amazon is legally defined as consisting of the whole of six states (Acre (AC), Amazonas (AM), Rondônia (RO), Roraima (RR), Pará (PA) and Amapá (AP) and parts of three others (Mato Grosso (MT), Maranhão (MA) and Tocantins (TO)). Only about three quarters of its 4,906,784 square kilometres contains rain forest. The remainder consists of savannah.

pare the report for the president, a task force was rapidly assembled and a building made over to it. In a vain attempt to prevent leaks to the press, INPE even moved its press officers away from the remote-sensing team.

Recalculation of the INPE figures using an estimate of the total area of rain forest (3,700,000 square kilometres) suggests that 6.8 per cent of the rain forest has been destroyed. But that figure is still much smaller than the 12 per cent deforestation claimed by the World Bank in its report *Government Policies and Deforestation in Brazil's Amazon Region*, released in January.

That figure is based largely on projections from Landsat data published in 1986 by Philip Fearnside, a US scientist working at the National Institute of Amazon Research at Manaus. But Fearnside himself estimates Amazon deforestation at 8 per cent. INPE's director-general, Márcio Noqueira Barbosa, says his institute's estimate is more accurate because it is based on 1988 Landsat images.

Landsat images are received every day at INP's station in Cuiabá, Mato Grosso. INP remote-sensing director Roberto Pereira da Cunha's team used Landsat Thematic Mapper data, with 30-metre resolution in the visible and near-infrared regions, to compile its data on deforestation. Cunha, who is clearly shaken by the controversy caused by the data, says they have studied 234 images, of which 104 were selected for detailed interpretation because they contained deforested regions. He claims the research began in August 1988 but this too is disputed. Other scientists say work began in earnest only in late March this year.

## SSC

## India offers help

### New Delhi

INDIA is proposing to participate in the US Superconducting Super Collider (SSC) project by contributing manpower and equipment but not money, according to Science Minister K. R. Narayanan. He told parliament last week that informal discussions had taken place between Indian and US scientists but "no formal agreement has been signed nor any commitment on expenditure agreed to".

Narayanan said India was joining the SSC project because it provided "a good opportunity for Indian scientists to work at the frontiers of science and technology".

A spokesman for the Indian team negotiating with the SSC project authorities confirmed an Indian offer of \$50 million in hardware, particularly particle detectors, but "there is not going to be any monetary contribution at all", he said.

## CLIMATE

## Worldwide atmosphere authority resisted

### Paris

AN official advertisement in French newspapers setting out the declaration signed by 24 nations at last month's environment conference at the Hague (see *Nature* 338, 193; 1989) has provoked an angry reaction in Brazil. The advertisement appeared on Monday, 3 April in all 24 signatory countries, but the version in *Le Monde*, *Figaro* and *Libération*, published at a cost of FF1.8 million (\$290,000) to the prime minister's information service, reproduced the signatures of the 24 national representatives alongside an additional statement which, it seems, was not part of the declaration.

The statement says that the 24 signatories call for the creation of "a worldwide authority, invested with real decision-making and executive powers to save the atmosphere". The statement also says that the signatories are "ready to surrender part of their national sovereignty for the common good of humanity as a whole".

Paulo Tarso Flecha de Lima, the Brazilian diplomat whose signature appears in the advertisement, was not prepared to go this far at the Hague. The Brazilian government, criticized for destruction of its rain forests, has angrily resisted attempts by other nations to enforce a policy of conser-

vation. Brazilian President José Sarney recently accused the foreign media of conducting an "alarmist campaign" against Brazil and complained that developed countries were backing policies that would make Brazilians "slaves".

The United States, which did not send a representative to the Hague meeting, also has no enthusiasm for a new worldwide authority. At a congressional briefing last week, William A. Nitze, a US State Department representative, said it was "premature to be considering a 'law of the air' or supranational authorities to deal with climate change".

With European elections in full swing in France, concern for the environment has become a campaign issue. Opinion polls following a good result in recent municipal elections have shown the hitherto dormant French ecology party to be an emerging alternative centre force and both the incumbent socialists and the right-wing opposition have been scrambling to demonstrate their interest in environmental issues. That may partly explain the government's decision to advertise the Hague declaration with President François Mitterrand's signature prominently on display.

## New sales tax hits science

### Tokyo

JAPAN'S controversial new sales tax, which came into effect last week, has not only placed an additional burden on Japan's consumers but has also pushed up the costs of scientific research. The budgets for the science-related ministries have been increased over the past few months to cover some of the costs of the new tax, but universities and research institutes will still find themselves worse off.

The sales tax marks the most sweeping reform of Japan's tax system since the Second World War and has met almost universal opposition. Although set at a low overall rate of 3 per cent, the tax covers almost all forms of 'consumption'. Books, food, transportation, rent and even the costs of childbirth and tombstones are taxed. Scientific research is no exception.

Although the tax takes up only a small percentage of ministerial budgets, it does constitute a significant proportion of the increase in outlay for science between the fiscal years 1988 and 1989 — about 20 per cent, or ¥5,900 million (\$45 million), in the case of the Science and Technology Agency.

The tax is levied on the purchase of equipment, books and journals and also adds significantly to the cost of construction of new facilities. Although the various science-related ministries have made upward revisions in their budgets to cover the tax, some of the burden will inevitably have to be borne by the universities and research institutes.

For example, although the Ministry of Education, Science and Culture has raised the budget for fiscal year 1989 for grants-in-aid of research to cover the increased costs of equipment, the value of multi-year grants awarded before implementation of the tax (for example, the 'special distinguished grants' which run for 3–5 years) will remain unchanged.

The new tax has helped to make Noboru Takeshita the most unpopular prime minister in the post-war era. The latest polls show that less than 10 per cent of the public support his administration. And revelations last week that Takeshita received almost ¥100 million (\$760,000) in donations from the scandal-ridden Recruit company in the run-up to his election as head of the ruling Liberal Democratic Party (LDP) have further weakened his position.

Calls for Takeshita's resignation are growing within the LDP and he may not be able to survive in office for longer than a few more months. Under a new leader, the sales tax could be revised, but as it has taken the LDP ten years and two failed attempts to introduce it, the tax seems likely to remain.

David Swinbanks

## More yen for joint research

### Tokyo

LEGISLATION at present before Japan's Diet will allow the Science and Technology Agency to launch a new international programme in October to promote joint research with overseas institutions. The new programme will for the first time open a way for Japanese government money to be spent on research facilities in foreign countries.

The new research initiative will be modelled along the lines of the agency's Exploratory Research for Advanced Technology (ERATO) programme, which recently received high marks in an assessment by US researchers (see *Nature* 337, 196; 1989). ERATO, which is run by the agency's Research and Development Corporation of Japan (JRDC), finances 'high-risk' research with potential for application. Although some foreign scientists participate in ERATO, the research is carried out entirely within Japan. The new 'international ERATO' will allow participation by overseas research organizations (in government, industry and university) through cooperative research agreements. Legislation allowing JRDC to establish such agreements is expected to pass through the Diet within the next month or two, say agency officials.

The programme will support teams of about 20 researchers, about half based in Japan and half overseas, with funds of about \$8 to \$13 million for periods of 3 to 5 years. Agency officials hope that participating countries will contribute research funds and facilities as well as researchers, although it is possible that JRDC will 'rent' research laboratories overseas as the corporation now does in Japan for ERATO.

Until now, it has been almost impossible for Japanese government organizations to spend money on research facilities in foreign countries because of the lack of rules and mechanisms for auditing and accounting. A classic example is the bureaucratic delay encountered by Tokyo Astronomical Observatory in its attempts to build the world's largest telescope in Hawaii (see *Nature* 311, 5; 1984). After years of debate, the telescope has still to win government approval. By renting rather than buying research facilities, agency officials are confident they can avoid such problems.

Masahiko Noda of the agency's International Affairs Division says the programme received a favourable response in the United States last month when he visited various organizations, including the Office of Science and Technology Policy, the National Science Foundation, universities and non-profit research institutions. And Kaname Ikeda, director of the division, says a research project with the

United States could be set up within a few months using the new mechanisms created under the US-Japan Science and Technology Agreement signed last June.

But some difficulties may be encountered in trying to apply the ERATO model to the United States. ERATO projects are headed by senior Japanese scientists hand-picked by JRDC, an approach that runs counter to the open and competitive research system of the United States. And agency officials admit that they will probably have to adopt a more "flexible" approach in foreign countries than that used in Japan.

Apart from international joint research projects, the new organization in JRDC will administer the agency's new post-doctoral fellowship scheme for foreign researchers which began last year (see *Nature* 335, 287; 1988), and will provide accommodation, Japanese language training, counselling and information for overseas researchers working in Japan. The agency has set aside ¥418 million (\$3.2 million) for the programme in the second half of fiscal year 1989 and about ¥800 million to build 50 homes for foreign researchers in Tsukuba Science City by 1991.

David Swinbanks

### HIGHER EDUCATION

## Vet schools reprieved in Britain

### London

FEARS that two of Britain's six veterinary schools may have to close receded last week when the Universities Funding Council decided to ask the Ministry of Agriculture, Fisheries and Food (MAFF) to reconsider future manpower requirements in the veterinary profession. A review is expected to show that previous forecasts of manpower needs were too low and that all six schools are necessary.

A report published in January recommended the closure of the veterinary schools at the Universities of Glasgow and Cambridge and the redistribution of their staff to the remaining four schools (see *Nature* 338, 191, 16 March 1989). But the British Veterinary Association now argues that more students are needed and that earlier estimates it gave to MAFF were wrong.

The decision was welcomed by James Armour, head of the veterinary school at the University of Glasgow. But he remains dissatisfied that the recommendation to close Glasgow was partly based on its proximity to Edinburgh, where there is another veterinary school, rather than solely on academic performance.

Christine McGourty

## ALASKA OIL SPILL

# Fisheries first to suffer

## Berkeley

A HUGE clean-up operation continued last week in Alaska's Prince William Sound, the site of the largest oil-tanker spill in US history. As the main oil slick moved southwest, out of the sound, it left behind smaller slicks, hundreds of miles of contaminated shoreline and more than 1,400 square miles of fouled waters. The wrecked tanker *Exxon Valdez* was floated from the reef where it had run aground and towed to a nearby island for repairs.

The captain of the tanker, Joseph Hazelwood, is said to have been under the influence of alcohol and absent from the bridge at the time of the accident. Coast Guard investigators were told by at least one crew member that Hazelwood had placed the ship on automatic pilot on an erroneous collision course with the reef.

Hazelwood, wanted in Alaska on misdemeanor charges associated with the spill, surrendered to the authorities in his home state of New York last week. A New York judge set his bail at \$1 million, after pointing out the magnitude of the disaster, but a second judge later reduced bail to \$25,000.

The oil contaminated a large portion of the herring-spawning grounds in Prince William Sound. Last week, Alaska Fish and Game officials cancelled the herring-roe fishery that would normally have opened several weeks ago. Paul Ruesch, a state fisheries biologist, said both herring eggs and young larvae are highly susceptible to toxic hydrocarbons. "We couldn't justify additional mortality from the fishery", he said. There is also a risk that the roe may be contaminated and therefore unsaleable. The fishermen, who stand to lose \$12 million, hope to recover damages from Exxon.

This year's \$70-million salmon fishery, due to begin in early summer, may escape serious damage from the spill, but the catch in future years is likely to be reduced if the oil affects this year's young. Fishermen continued to set floating booms to keep oil out of the bays that house the area's four salmon hatcheries.

But Ruesch acknowledged that success with booms has been "spotty", and the hatcheries are largely at the mercy of the winds. If large amounts of oil come their way, salmon fry reared in captivity may be caught at a vulnerable stage when they are being transferred to salt-water pens ready for their May release. Wild fry which are beginning to emerge from gravel beds will also be at risk.

The level of toxins in the sound, and their effect on the plankton, is not yet known, as water sampling has just begun. Various agencies are preparing for long-term studies of the effects of the oil on water quality, sediments and beaches.

"There will undoubtedly be some very long-term persistent impacts", said Ruesch. "Prudhoe Bay crude does not weather well; it doesn't break up and it doesn't sink. It is very persistent."

The sound has the largest concentration of sea otters in the world, according to Mark Kuwada, a habitat biologist with the fish and game department. Kuwada said that 30 per cent of the sound's 5,000 sea otters live in areas affected by the spill, although it is not known how many have died.

Thousands of waterfowl have been killed by the oil, and the sound's large population of endangered bald eagles has been reported to be feeding on the contaminated carcasses, although no dead eagles have yet been found. Two deer were found dead after apparently feeding on seaweed tainted with oil.

President Bush last week made available US military troops to help clean up the spill, acknowledging that Exxon's efforts were insufficient. He emphasized that the government was not "federalizing" the clean-up operation, and that Exxon would still be responsible for costs.

Environmentalists say an accident such as this was inevitable, given Alaska's laxity in monitoring the oil industry, which supports 85 per cent of the state's economy. Mike Matz, of the Sierra Club, said Alaska's Department of Environmental Conservation, which is responsible for approving the oil industry's contingency plan for clean-up of spills and for assuring that the industry maintains the promised level of preparedness, lacks adequate funds and has been unable to carry out adequate monitoring. Even when permit violations were discovered, said Matz, political pressures prevented prosecution of the violators.

Although the spill has not changed the Bush administration's support for oil exploration in Alaska's Arctic National Wildlife Refuge (ANWR), public outrage over the accident has slowed the progress through Congress of a bill to authorize the exploration, while both houses hold hearings on the causes and potential effects of the accident. Congressional representatives from California have used the spill to fuel their protest against the opening of areas off the California to oil exploration. Interior secretary Manuel Lujan Jr warned oil industry representatives last week that the *Valdez* accident could have an effect on the oil industry similar to that of the Three Mile Island accident on nuclear power. "If the image of an uncaring and uncaring industry prevails among the public", he said, "then we can kiss goodbye to domestic oil and gas development in ANWR, offshore, and in the public lands."

**Marcia Barinaga**

## FRENCH RESEARCH

# Worries about future

## Paris

THE French research minister, Hubert Curien, has set up two working parties with unions representing researchers to find ways to protect the future of their profession. One will consider the problem of recruitment of young researchers to the major state research organizations, such as INSERM and CNRS, while the other will look at career prospects, with the accent on greater mobility of trained researchers towards universities and industry.

The unions are pessimistic about the negotiations. Robert Descimon, general secretary of SNCS, the biggest union representing full-time researchers, fears that the government is dismantling the state research organizations in favour of the universities, whose research role in many disciplines is relatively small. Most research is carried out in state organizations, where researchers have jobs for life and a small teaching load. But a slowing in the number of new posts has created a bottleneck of young postdoctoral researchers seeking their first job, with a resulting rise in the average age of researchers. Meanwhile, salaries are becoming increasingly unattractive compared with those offered by industry, even to untrained researchers.

In his pre-election "letter to the French people", President François Mitterrand declared that research would be a national priority. "There is not much evidence of this so far", says Descimon. Most of the government effort, he says, is directed towards major reforms of education, including higher education. The unions fear that trained researchers will be drained from the state research organizations in order to inject new blood into the universities, without the promised reevaluation of research as a career.

Peter Coles

## JAPAN

# Electronic Leonardo

## Tokyo

JAPANESE art lovers who want to see the Mona Lisa but cannot make the trip to the Louvre may soon be able to enjoy the next best thing. A new art gallery in Gifu, central Japan, is using high-definition television (HDTV) to display works of art recorded digitally on compact discs.

HDTV, which was first developed by Japan's National Broadcasting Corporation (NHK), has twice as many lines on the screen as conventional television and produces images of exceptional clarity.

The Gifu Museum of Fine Arts is using the system to show pictures from its collection which it does not have room to put on display. In the future, museum officials hope to import HDTV images from art galleries all over the world so that visitors will be able to view famous works of art at the push of a button.

David Swinbanks

## Activists attack in Arizona

### Tucson

ANIMAL rights activists broke into four buildings at the University of Arizona on 3 April and set two fires, vandalized laboratories and kidnapped 1,000 animals to protest against the use of animals in research. University officials said that structural damage amounted to \$110,000 and estimates of the total damage go as high as \$250,000.

In press releases left at local newspaper offices and radio and television stations, the Animal Liberation Front claimed responsibility for the arson and damage. A fire in a rooftop laboratory of a five-storey pharmacy-microbiology building gutted two rooms and damaged two others, causing a total of \$90,000 damage. That fire took an hour and 46 firefighters to get under control.

A second fire was started in the crawl space under the small house containing the animal resources administrative offices and caused \$10,000 damage. Clyde S. Card, director of the Arizona Diagnostic Laboratory, said that about \$125,000 damage had been done to that laboratory's autopsy room and three veterinary science laboratories.

Vandals also smashed windows and ransacked laboratories in a neighbouring building and in another a block north of the pharmacy-microbiology building. They spray-painted slogans including "Nowhere is safe", "We shall return", "You are killers" and "Torture teaches nothing" in red on the walls and floors. Pet food was strewn over one basement.

The group's statement said that a thousand animals were liberated as an act of mercy and compassion for the individual animal victims and that laboratories were damaged to protest against vivisection. The statement claimed that the action was part of an international campaign against misguided efforts by the scientific and medical industry.

'People for the Ethical Treatment of Animals', an animal rights organisation based in Washington, DC, later provided television stations with a video of the break-in, showing black-hooded individuals loading animals into boxes and smashing windows with hammers. The group took about 1,000 mice, 50 rats, 175 rabbits, 4 frogs and several guinea pigs. According to the animal activists, the animals were being placed "in good homes around the country where they will live free from the invasive curiosity of researchers and vivisectionists".

About 30 of 340 mice taken from one building were infected with *Cryptosporidium*, a protozoa that causes severe diarrhoea, according to Charles Sterling, a professor of veterinary science.

The mice were being used in a study

supported by the US Environmental Protection Agency to test the effectiveness of disinfectants against this waterborne parasite. Those who handle the mice may suffer from severe diarrhoea for two to four weeks.

Other affected work included genetic studies of heat stress, studies of the long-term effects of selenium-deficient diets, research on a vaccine for swine dysentery and studies of the effect of diet on protein metabolism. Scientists involved estimated that the loss of animals set the projects back months, and perhaps years.

The Animal Liberation Front group may have been helped by people inside the university as they appear to have known where and how the animals were housed, according to Michael Cusano-vich, University of Arizona vice-president for research. The group is thought to have broken into one building by forcing open a vent. Police were not sure how the group gained access to the other buildings. The Federal Bureau of Investigation is also involved in the case.

In January, animal activists claimed responsibility for taking seven dogs used in heart research at the Tucson Veterans Administration Hospital.

**Elizabeth Pennisi**

## Municipal law on its way

### Boston

WITH recommendations from an advisory panel due this week, the city of Cambridge, Massachusetts, moves one step closer to passing the first local ordinance in the United States to provide municipal control over the care and treatment of laboratory animals. While it is still too early to know precisely what provisions the law will entail, it is likely that the city council will pass legislation this spring.

The new recommendations come from a panel established by the city council in the autumn of 1987 to evaluate the treatment of laboratory animals at facilities in Cambridge. Among those facilities are several belonging to the Massachusetts Institute of Technology (MIT).

The three-member panel, which includes a local veterinarian and representatives from the scientific community and animal rights groups, found no instances of cruelty or abuse of animals in Cambridge laboratories. But the group is still split over the adequacy of existing regulatory mechanisms in the city.

Because of the disagreement, the panel delayed release of its recommendations to the city council. But the pressure is on for city officials to act on the issue. Under consideration are provisions which would give a local animal commission the power to uphold "the community's ethical standards for the use of animals in experiments". The local authority would investigate alleged violations of local standards for the care of laboratory animals and fines to research institutions that failed to comply. A further provision to be considered by the city council would require researchers who handle animals in laboratories in Cambridge to take a course from the local animal commission on the new standards.

John Moses, an MIT physician who heads the university's animal care committee, represented the scientific community on the advisory panel. He stresses

that the panel's lack of evidence of animal abuse argues against the need for local legislation. But he believes the panel is "very close" to making recommendations that all three representatives can agree upon. The recommendations should give a clear guide as to the severity of the city council's actions.

The council has already taken interim action. Nearly two years ago, when the advisory panel was formed, it banned outright within city limits the use of two common animal toxicity tests, the Draize test and the LD 50 test. Animal rights groups have already proposed strong city legislation to regulate practices involving laboratory animals; the panel's forthcoming recommendations are seen as offering the potential of a politically viable compromise.

With the week of 24 April designated by animal rights activists as 'world week for lab animals', increased public attention is expected. In Massachusetts, organizers say they plan to hold demonstrations aimed specifically at the Gillette Corporation because of the company's use of animals in the development and testing of its products.

In New York, for the third year in a row, protesters plan to target their demonstrations at New York University. Animal rights groups have singled out the research conducted by Ronald W. Wood, professor in the department of environmental medicine. Wood, who studies the effects of the inhalation of toxic substances including crack and cocaine, as well as organic solvents, uses rodents and some primates in his research. Last year's demonstrations in New York drew more than a thousand protesters.

Wood says he believes most are "well intentioned, but misguided". "My work", he says, "tries to provide information about very real human problems of drug abuse and occupational hazards."

**Seth Shulman**

## Different ways with *glasnost*

London

Mr Mikhail Gorbachev, the Soviet president and Party general-secretary successfully tied up London traffic for two days last week, made a speech at the Guildhall, had lunch with the British Queen, who accepted his invitation to visit the Soviet Union at a "convenient" time.

The official visit to London followed one to Cuba, both of which had been postponed in December on account of the Armenian earthquake. But the changed itinerary allowed Gorbachev to meet the Prime Minister of the Irish Republic during a stopover on the outward journey.

The three visits showed some interesting contrasts in the exercise of *glasnost*. In Ireland, Gorbachev stressed his concept of a "common European home" in language apparently innocent of Ireland's jealously guarded neutrality, but agreed with Mr Charles Haughey on further economic collaboration in fishing, shipbuilding and barter in food products.

Gorbachev promised to raise in London two human-rights issues arising from the continuing conflict in Ulster (Northern Ireland), but declined to suggest a political solution for the conflict.

In Cuba, where President Fidel Castro has so far proved remarkably resistant to *perestroika*, the emphasis was on continuing friendship. The two leaders signed a new treaty of cooperation in science and

technology, and promised improved contacts in "science, culture, education, health-care, the press, radio, television, cinema, tourism and sport".

But Gorbachev gave a clear warning against the "export of revolution" from Cuba to Latin America and visited a science exhibition showing a new high-powered sugar-cane harvester, a micro-analysis system for blood testing and a model of the Juragua nuclear power station being built with Soviet assistance.

In Britain, Gorbachev used his Guildhall speech to announce that the Soviet Union has ceased the production of weapons-grade plutonium, and that it is about to do the same for weapons-grade uranium. This was described by the US State Department as an "empty gesture" on the grounds that the recycling of existing stocks of fissile material should suffice for many years to come. Mrs Thatcher, the British Prime Minister, rather emphasized her view that nuclear weapons provide a stronger peace-keeping deterrent than conventional forces.

On the human rights front, the Gorbachev visit was marked by the arrival in London of mathematician Georgii Samoilovich, long denied an exit visa on the grounds of his access to classified information 17 years ago. He is to undergo urgent treatment for a leukaemic condition.

Although the Soviet and British governments agreed during the visit on further cooperation in the arts and trade, little was said at the formal level about science and technology. The Soviet offer to find a place on a future space mission for a British astronaut, now made unconditionally, seems to have run into British unwillingness to meet the costs entailed.

Professor Vitali Goldanskii, director of the Institute of General Physics in Moscow, well-known in Britain as the chairman of the Soviet Pugwash committee, was prominent among Mr Gorbachev's advisers during the whole week. As one of the first to recognize that some radioactive nuclei may emit particles heavier than  $\alpha$ -particles, he was one of those who visited the Atomic Energy Research Establishment to inspect the still-negative attempts to replicate electrolytic fusion. He was also eager to explain to all enquirers how he proposes, as part of *perestroika*, to split his Moscow institute into several autonomous units, each with a separate director.

Gorbachev himself visited a British factory manufacturing communications equipment supplied to the Soviet Union — and *Izvestia* took the occasion to lecture the West on the iniquities of the Cocom ban on the export of sensitive technology to the Socialist bloc.

Vera Rich

## Remote-sensing satellite for Iraq

São Paulo

Brazil's Institute of Space Research (INPE) is considering a proposal to build a remote-sensing satellite with military potential for Iraq. Brazil was an important supplier of arms to Iraq during the Iran-Iraq war.

INPE, together with Brazil's aircraft manufacturer, Embraer, and private companies would build the body of the satellite using technology INPE has acquired for its own programme to construct four satellites. Brazil will have its first satellite ready by the end of the year, although it may have to wait until 1992 for an indigenous launch. The development of the Satellite Launch Vehicle by the Air Force is behind schedule.

The first two Brazilian satellites will be small (115 kg) test capsules. Remote-sensing satellites of similar size will then be launched. INPE also has an agreement with China to design a bigger remote-sensing device.

Iraq is thought to be interested in help in establishing a satellite-building and testing facility. The sophisticated camera required for military sensing would come from a French company. But the deal appears to be encountering opposition inside Brazil's Foreign Ministry. INPE's director-general, Marcio Nogueira Barbosa, said he would prefer to pass INPE's satellite-construction technology to private companies.

Ricardo Bonalume Neto

## Study planned of greenhouse effect

Sydney

A YEAR after rejecting a request for A\$1 million to support research into the greenhouse effect, the Australian government has changed its mind and agreed to spend A\$7.8 million on the same topic over the next 15 months.

The Prime Minister, Bob Hawke, explained the turn-around by stressing the "dramatic explosion of awareness" of the greenhouse effect over the last year.

Part of the A\$7.8 million will be used to set up a National Greenhouse Advisory Committee of six experts to help the government to set research priorities. A\$5.54 million will go to the Commonwealth Scientific and Industrial Research Organization (CSIRO) and the Bureau of Meteorology to continue research into predictive modelling. The remainder will support Australian participation in international research programmes.

The government has also promised to help countries in the Pacific region that will be affected by changes in sea level.

Tania Ewing

### NEWS IN BRIEF

## New radiotelescope

Bangalore

Under a new agreement, India and the Soviet Union will jointly fabricate and install a radiotelescope in South India.

The telescope will form part of an eastern hemisphere very-long-baseline interferometer. It will be linked to the baseline connecting similar radiotelescopes at Ussurisk and Ephratoria in the Soviet Union.

## Prisoners freed

Washington

TWELVE Somali scientists, engineers and medical doctors were freed from prison earlier this month, according to two committees of the US National Academy of Sciences and the Institute of Medicine which had taken up their cause. A report published by the two committees last year accused the Somali government of torturing prisoners and of detaining them for years without formal charges (see *Nature* 331, 196; 1988). Somali Prime Minister Lt General Mohamed Ali Samantar promised in a speech in Washington last month that his government would release the prisoners.

J. P.

## Having the final word. . .

SIR—I do not know whether there are still Creationists who believe that God created the world with implanted fossils and strata records (and similarly a Universe with implanted galactic records); but, if there are, then Bruce Denness's letter "Divine artefact" (*Nature* 336, 614; 1988), raises a problem that should be of great concern to them.

"God is not a man, that He should lie" (Numbers 23:19). Yet the suggestion that God could have created a world, or Universe, in which a record of the past was 'implanted', implies that he has lied. And the consequences to faith could be more shattering than they are to science.

First: if (*arguendo*) the Earth and Universe are (say) only 20,000-odd years old, but have been created to appear respectively about  $5 \times 10^9$  and  $20 \times 10^9$  years old, then these greater ages are without doubt their *scientific* ages — there is no way that science can come up with an age of 20,000 years. To understand this, consider what the *scientific* ages of brand-new but exact copies of this Earth and Universe would be, if God chose to make such copies.

Second, it becomes a matter of faith alone, under such circumstances, that the age of the Earth or Universe is anything other than what it appears to be scientifically. And only faith can govern the selected age. But why, under such circumstances, should any particular age be arbitrarily chosen? Creationists may interpret the Bible as implying one age rather than another; but the Earth could have been created *some year ad* with Bibles intact as part of the implanted record. How is one to prove that that did not occur? But if it did, then Jesus was not born on Earth and did not die for us; nor was he resurrected. What happens, then, to our salvation? So, to believe that God could have created an Earth or Universe with an implanted record ultimately strikes at the heart of the Christian faith. Maybe quite a headache for Creationists.

Perhaps there is no scientific answer to the problem Denness raises, but only a theological one.

JOHN BLASDALE

Whippany, New Jersey 07981, USA

SIR—I find that it has become necessary, for a second time (see *Nature* 323, 754; 1986), for Me to intervene in order to present My Word in these pages.

Unless I have misunderstood matters (which is unlikely), I am depicted by some individuals as a sort of Divine Con-Artist (*Nature* 336, 614; 1988 and 337, 498; 1989), allegedly creating the Universe, and then disguising this fact, for reasons apparently known only to Myself. Others find it beholden upon themselves to rush

to My defence and deny this, because they have decided that it reflects poorly on My Divine Logic.

I had hoped that My previous Correspondence in these columns had made clear that *all* speculation of *any* kind on My Nature is unwelcome, from both an epistemological and a Personal view. In particular, if ever again I read Professor Einstein's remarks to the effect that, whilst I am Cunning, I am not Malevolent, the extent of My lack of malevolence will be sorely tested. It is not that I disapprove of Professor Einstein's flattering description, it is that even My Patience, Infinite though It is known to be, is beginning to crack at the many, many repetitions I see of that comment. One other observation I hope never to be quoted again, at least for a long time, is Professor Haldane's, the one about the cosmos being not only stranger than one imagines but . . . you know how it goes. Whilst apposite, I feel it needs a rest.

But I digress (which is one of the qualities One finds in Omnipotence).

A periodical ostensibly concerned with matters of scientific interest would do well to think carefully before allowing speculations of a totally metaphysical nature space in which to appear. I certainly would hope that I am as disposed to be as Broad-minded as the next Entity and that no-one would accuse Me of desiring to fetter a free press, particularly in this country at this time, but I commend the matter to your most earnest consideration, if you get My drift.

I trust I shall not have to bring this to your attention on a third occasion.

God

## Intuitive science

SIR—I have been reading *The Value of Science* by Henri Poincaré, who believed that intuition and logic make science advance. Intuitive scientists work in figures and imagination; in mathematics, they are its geometers. Logic scientists go from the particular to the general; they are the analysts in mathematics.

As a biochemist who agrees with Poincaré, I ask: what is the contribution of logicians and analysts to the advance of biochemistry? From the biochemical journals, it seems that only logicians exist. All hypotheses, even if they are subsequently shown to be wrong, are based on experi-

mental results presented in a formal and statistically rigorous way.

I believe that intuitive biochemists exist, but that their contributions have to be communicated in the form required by the journals, in analytic form. Hypotheses that are intuitive in nature are not considered suitable for biochemical journals.

Yet Poincaré points out that intuitive work is even more important than analytical work for the advance of science. In biochemistry, it sometimes seems that analytical work is performed without any precise objective. The thousands of articles in the journals contribute very little to the advance of knowledge. That is why two urgent needs in biochemistry are (1) the study of all the available information in order to advance intuitive hypotheses and (2) the recognition and promotion of intuitive biochemists through publication of that work. To these ends, journals should change their policies without lowering their quality.

Poincaré said it clearly: "Pure logic does not lead to anything but tautologies; it creates nothing new".

## History lesson

SIR—You remark in your unsigned Commentary article marking the fiftieth anniversary of the discovery of uranium fission<sup>1</sup> that to suppose that "some history is so painful that nothing can be learned from it . . . is a disservice to the intellect" bears on three items in the previous issue of your journal<sup>2-4</sup> dealing with quark matter and strange matter. In the News and Views piece on the subject<sup>2</sup>, we find the statement that the growth phase of quark nuggets caused by the addition of low-energy neutrons "releases of the order of 20 megaelectron volts of energy yield per captured neutron . . . nearly 10 times the yield per neutron in a conventional fission reactor".

Let us hope that the human intellect has matured enough in the intervening 50 years to learn from past experience; and that if the proposal of Shaw *et al.* for quark matter engineering turns out to be successful, you will be able to write a different kind of Commentary for *Nature* in 2039.

### Mouse Anti-Human Ki-67 Antigen DAKO-Ki-67 (DAKO-PC)

**Left:**

Immunoblastic lymphoma of B cell type labelled with DAKO-Ki-67, Code No. M 722 by the APAAP procedure. The majority of the tumour cells show a positive reaction of their nuclei.

**Right:**

Con-A-stimulated lymphocytes labelled with FITC-Conjugated DAKO-Ki-67, Code No. F 788, and RPE-Conjugated DAKO-CD2, Code No. R 807 in Flow Cytometry.

Y-axis: Number of cells.

X-axis: DAKO-Ki-67/FITC.

Z-axis: DAKO-CD2/RPE.

- Reacts with a human nuclear antigen present only in proliferating cells
- Reacts with cells in late G<sub>1</sub>, S, M and G<sub>2</sub> phases, but not with cells in G<sub>0</sub> phase
- Provides a reliable means of evaluating the growth fraction of human neoplasms
- Enables a reliable identification of proliferating cells in cell suspensions by two-colour immunofluorescent staining
- Available as supernatant for immunoenzymatic staining techniques and for indirect immunofluorescence techniques, DAKO-Ki-67, Code No. M 722
- Available as FITC-conjugated monoclonal antibody for flow cytometry, DAKO-Ki-67/FITC, Code No. F 788

# Amplify your DNA with new AmpliTaq from Perkin-Elmer Cetus.

The new AmpliTaq™ Recombinant DNA Polymerase is a superior genetically engineered enzyme offering key advantages in the patented\* GeneAmp™ Polymerase Chain Reaction (PCR) technique including:

- ☐ A purer DNA polymerase by using state-of-the-art recombinant DNA production techniques
- ☐ The elimination of unwanted thermostable nucleases since the enzyme is not purified from a thermostable bacterium

Extensive studies have shown that the thermostability and specificity of the recombinant enzyme is similar to the native enzyme and can be substi-

tuted for native *Taq* DNA Polymerase for most PCR applications and DNA sequencing.

The new AmpliTaq DNA Polymerase is also available in the GeneAmp DNA Amplification Reagent Kit which has been optimized for the DNA Thermal Cycler – an instrument specifically designed for automating the temperature cycling required in the PCR process.

AmpliTaq™ and GeneAmp™ are trademarks of the Cetus Corporation  
IsoPure™ is a trademark of the Perkin-Elmer Corporation\*PCR is covered by US Patent No. 4,683,202 issued to Cetus Corporation  
Patents pending on DNA Polymerase and its use.

## PERKIN ELMER CETUS

# NIKON'S BRIGHT IDEA

The new MICROPHOT-FXA with epi-fluorescence attachment opens up a new dimension in fluorescence microscopy.

Fluorescence microscopy is gaining wider attention and increased use thanks to its high specificity and high sensitivity.

The Nikon MICROPHOT-FXA is ideal for this type of work thanks to its Direct Projection System which enables utilization of 100% of the light from the specimen and requires astonishingly short exposure time. In addition, the newly designed extra-bright illumination system further increases versatility by permitting photomicrography of even the faintest fluorescence images.

If seeing is believing, then one look at the new MICROPHOT-FXA will convince you — it's the right choice.

# Hot-footed towards cold fusion

The only published account so far of thermonuclear fusion in an electrochemical cell raises, as its authors say, "more questions than it provides answers".

THERMONUCLEAR fusion, which allows stars to shine, must also occur in more humdrum circumstances. Put two deuterons together in a deuterium molecule, for example, and there is a small chance that they will fuse together spontaneously, either to produce a tritium nucleus and a proton or a helium-3 nucleus and a neutron. Perhaps luckily, the chance is astronomically small, maybe  $10^{-70}$  per molecule per second. At that rate, there would be roughly one fusion event an hour in a quantity of molecular deuterium roughly as massive as the Galaxy.

The reason why muons have been advocated as catalysts of fusion is that their mass (some 200 times greater than that of an electron) makes for a smaller  $D_2^-$  ion, thereby increasing the wave function of one deuteron at the position of the other and so increasing the still-random chance of fusion.

The great excitement in the past three weeks about the prospect that thermonuclear fusion has been accomplished electrochemically is an extension of this principle. The article by M. Fleischmann and S. Pons which appeared last week (*J. Electroanal. Chem.* **261**, 301; 1989) begins from the view that conditions favourable for fusion may be created electrochemically by exploiting the familiar affinity of palladium for hydrogen (in all its isotopic forms).

As described, the experiments seem straightforward. Use a platinum anode, a palladium cathode and an electrolyte which is a heavy-water solution of deuterated lithium hydroxide. To prevent the deuterons bubbling away as deuterium, arrange that there is a substantial negative over-voltage on the cathode. The effect is that deuterons accumulate in the palladium lattice, and will continue to do so until their conversion into molecules resumes.

That point, Fleischman and Pons argue, is determined by the chemical potential of the deuterons in the palladium lattice, which is itself determined by the negative over-potential on the cathode. They use the term "galvanostatic compression" to describe this process of forcing deuterons into the palladium.

Three kinds of measurements are described, one of which is simple calorimetry. The question is whether the heat produced in such a cell is greater than expected, which is most simply that calculated

by multiplying together the current and the voltage.

The article describes measurements with cells containing electrodes of different shapes and sizes. For three-rod electrodes of different diameters, the specific rate of excess heat production is reported to have increased with increasing current density and with the thickness of the rod (4 mm at its maximum), both of which argue for a phenomenon liberating excess heat in which the bulk of the palladium is involved. There is also an account of how, in one experiment, the cathode (a 1 cm cube of palladium) vaporized.

True fusion should of course be recognizable in other ways, by the detection of its by-product particles for example. The authors report measurements of  $\gamma$ -rays presumed to have occurred by the reaction of neutrons from fusion reactions with protons in the water-bath surrounding the electrolytic cell and also the detection of neutrons (at roughly three times the intensity of the cosmic-ray background) while one experiment was running. They have also looked for (and claim to have found) tritium in the residual electrolyte in a cell.

So does this not add up to a proof of fusion? From the details published so far, no-one can say. The nuclear evidences offered are all close to the edge of what is measurable. The measurement of tritium production, for example, looks convincing, but there are pitfalls. Any quantity of deuterium-rich water invariably contains the heavier isotope in some quantity. One is looking for a small increase in tritium content, rather than its mere presence where there was none before. Similarly, there are other sources of neutrons and gamma rays besides fusion reactions (notably cosmic rays and natural radioactivity), and these must be convincingly subtracted.

Even taking the  $\gamma$ -ray and neutron production at face value, far too few of either are recorded to explain the claimed heat generation by known fusion reactions. In one of the experiments described, the rate of production of excess heat suggests that there should be between  $10^{11}$  and  $10^{14}$  fusion events a second, but the nuclear physics data suggest that known fusion reactions (leading either to tritium or  $^3\text{He}$ ) account for only about  $10^4$  of these.

This is the most serious impediment to

belief. The heat production in these electrolytic cells is more than a million times greater than nuclear by-products would suggest it can be. This leads Fleischmann and Pons to say that "the bulk of the energy release is due to a hitherto unknown nuclear process or processes". What, one wonders, can that process be? Is it likely to have escaped the attention of nuclear physicists in the past half century?

Sceptics, in the circumstances, will be quick to ask whether the necessary subtle subtractions from the gross energy output have been accurately made — the electrical energy put in, the heat that would have been produced in a normal electrolytic cell (with ordinary hydrogen instead of deuterium) and so on. Because Fleischmann and Pons spend days, perhaps weeks, loading their electrodes with deuterium, there is plenty of energy stored up in their system before any return is obtained. Even the much-described "explosion" of one of their electrodes may be explicable by chemistry.

By now, the tiny band of *Nature* referees which has scrutinized the two articles submitted for publication has been joined by many other people. Further information about the issues which have given them difficulty will be given in a further issue of *Nature*. Numerous attempts to replicate the measurements have produced only one positive claim (see page 529). One common complaint has been that the data provided are insufficient to allow faithful reproduction of the measurements reported. The Fleischman and Pons article as now published is a starting-point for other experiments, but says less than the average chemist needs to know.

A more perplexing circumstance is that the authors are reported to have said that some cells work and others do not, although that may not be surprising when so little is known of the system as a whole. The idea that cells produce excess heat only after they have been running for long periods makes sense if a palladium lattice must be charged with deuterons before fusion occurs at anything like a decent rate, but one is left wondering whether the amount of charging needed can be predicted in advance for a given cell geometry and voltage, as one would expect if such a straightforward explanation were the only one. What seems plain is that arguments like these will continue for a long time. □

# Where is the Great Attractor?

N. Kaiser

SIGNIFICANT deviations from pure Hubble expansion of the Universe have been revealed by studies of the motion of elliptical galaxies. These have been attributed to the gravitational influence of the 'Great Attractor' — an extended mass distribution whose centre lies at a distance of about  $40 \text{ Mpc } h^{-1}$  (the nearest galaxy, for comparison, is about  $\frac{1}{2} \text{ Mpc } h^{-1}$  away). The precise scale of this mass excess is the subject of intense debate, with some studies preferring a somewhat smaller distance. Two groups, however, Scaramella *et al.* on page 562 of this issue<sup>1</sup> and Lahav *et al.*<sup>2</sup>, have found a strong concentration of rich clusters of galaxies in the direction of the Great Attractor, but at the much greater distance of about  $140 \text{ Mpc } h^{-1}$ . Although the gravitational pull of these objects themselves is probably too small to account for the motions, they may be indicative of an extension of the 'supergalaxy' to a much larger scale than previously thought, with important consequences for theories of structure formation. Alternatively, the alignment may just be a chance coincidence.

The existence of a Great Attractor was initially inferred from studies of the motion of elliptical galaxies<sup>3</sup>. These revealed that galaxies in the Hydra Centaurus region, which lie near the apex of the motion of the Virgo supercluster, and so had been suspected as the cause of this motion, were themselves moving in the same direction. This could be explained by the existence of a still more distant mass concentration, dubbed the Great Attractor. Spiral galaxies also show a significant motion in this region of space<sup>4</sup>: the line-of-sight motions for a compilation of spirals and ellipticals (D. Burstein, preprint) are shown in the figure.

Much effort has been devoted to discovering the Great Attractor directly as an excess in the space density of galaxies. One approach is to use redshift surveys to map out the three-dimensional distribution of galaxies and thus infer the acceleration acting on the Local Group of galaxies. These include an IRAS (Infrared Astronomical Satellite) redshift survey<sup>5,6</sup> and Dressler's survey<sup>7</sup> which concentrates on the Great Attractor region. An

alternative is to use the much larger catalogues which have apparent luminosities but no redshift information — the idea here is that as both light and gravity obey inverse-square laws, the dipole moment of the extragalactic light should be proportional to our acceleration and thus to our motion, provided that the surveys extend far enough to encompass the source of our acceleration.

These studies seem to confirm the

attraction of matter.

The theoretical implications of all this are less clear. A leading problem in cosmology is how the physics of the early Universe influenced the structure observed now (see also page 541). In particular, it is thought that fluctuations in the density of (perhaps unobservable) matter could have initiated the formation of galaxies and be responsible for the observed non-uniform distribution of the galaxies.

It seems, on the one hand, that the scale and amplitude of the mass profile implied by the Great Attractor are uncomfortable for the most popular cold-dark-matter model<sup>8,9</sup> (and this has stimulated interest

in alternative theories with extra large-scale power), but this is based on a rather literal interpretation of the model. The problem is that the Great Attractor model, which accounts quite well for the data, also makes predictions about the velocity field in regions where there is little or no data — on the far side of the Great Attractor for instance — so it is difficult to interpret this apparent discrepancy. On the other hand, the amplitude of the extragalactic light dipole moment agrees well with the predictions of cold dark matter.

A more recent development has been the application of correlation analysis<sup>10,11</sup>. The authors have tried to provide a measure of the scale and degree of coherence of the motions with a method similar to that used by Peeble in a powerful analysis of galaxy cluster-

ing. The conclusions here seem at first sight to be in conflict, but this is probably a consequence of the different weighting schemes used which mean that the statistics sample the velocity field at quite different distances. The less myopic sample<sup>10</sup> gives results which are not greatly out of line with the theoretical predictions. What is apparent from all these studies is that we do not yet have a sufficiently large survey to constitute a 'fair sample'.

Positions and line-of-sight peculiar velocities of local galaxies: box, centred on our Galaxy, is of side  $80 \text{ Mpc } h^{-1}$ . Hydra Centaurus lies in the upper-left quadrant, and the Great Attractor, as seen from the trend of the motions, is beyond the left edge. (Broken vectors, motion towards us; solid, away.)

existence of a significant excess of galaxies at about the right scale and direction. It is particularly impressive that the dipole moment of the extragalactic light agrees in direction with our motion to about  $10\text{--}20^\circ$ , and although there are differences — the IRAS redshift survey suggests a somewhat smaller scale for the attractor — the general impression is of a fairly consistent picture in which we can understand at least the gross features of the velocity field as the response to the gravitational

- Sutherland, W.J.S. *Mon. Not. R. astr. Soc.* **234**, 159–172 (1988).

Although the viability of the cold-dark-matter model, in the face of the velocities shown in the figure, remains very much an open question, the structures reported by Scaramella *et al.* in this issue<sup>1</sup>, which are also apparent in X-ray cluster catalogues<sup>2</sup> threaten a much wider range of theories. The major concentration of these rich clusters is so distant that it should not have contributed significantly to the acceleration inferred from either the redshift surveys or from the extragalactic dipole moment. In theories for the formation of structure which invoke gaussian random fields for the initial fluctuations that stimulated galaxy formation, one would not expect the mass excess at such distances to be aligned with the nearer mass excess, so even in theories with excess large-scale power the alignment seen is something of an embarrassment.

#### LYMPHOCYTE DIFFERENTIATION

## Not all in a name

Stephen Shaw

THE ambition of participants in the international workshops on leukocyte differentiation antigens has become nothing less than the definition and functional characterization of the entire array of cell surface molecules on human leukocytes<sup>1,2</sup>, which by the end of this year's meeting\* stood at a total of more than 78. These molecules now provide a fertile common ground, uniting the interests of immunologists, cell biologists, biochemists and those in other disciplines.

About half of the 33 newly classified molecules were previously unknown or quite obscure. For such molecules, the standardization of nomenclature and definition of reagents provides a starting point for investigation and collaboration. For some of them, the synthesis of information that occurred at the meeting was dramatic; arguably the most exciting was for a molecule now designated CD59. Based on functional, biochemical and molecular-biological approaches using two monoclonal antibodies (V. Horesji, Czechoslovak Academy of Science, Prague; G. Hale, University of Cambridge), the phosphoinositide-linked CD59 molecule is now thought to be the human homologue of murine Ly6c, a molecule capable of transmitting a T-cell activation signal<sup>3</sup>. Less direct evidence suggests that it is also identical to the molecule H19 (N4) which participates in T-cell adhesion to erythrocytes<sup>4</sup>.

The rest of the 'new' molecules were already reasonably well defined before the meeting. For some, such as LFA-3

These observations are not the first to suggest that the local supercluster is only part of a much larger structure<sup>1</sup>, and they lend support to this view. Whether this spells the end for conventional theories remains to be seen; perhaps the alignment is an acceptable chance occurrence; the X-ray cluster analysis involves a rather small number of objects, and the reliability of the Abell catalogue for these studies has recently been called into question<sup>11</sup>. Further studies are needed to establish the real extent of the supergalaxy, but have no doubt that in the meantime theorists will rise to the challenge and produce new theories to account for this tantalizing observation. □

N. Kaiser is at the Canadian Institute for Theoretical Astrophysics, University of Toronto, Toronto, Ontario M5S 1A1, Canada.

achieved by the workshop enriches our understanding of molecules by fostering cross-cultural exchanges of information regarding them.

In previous workshops of this series, the emphasis was largely in characterizing molecules whose expression is restricted to specific lineages of lymphoid cells such as CD3 (T3), CD19 (B4) or CD13 (MY7). In the present workshop, the emphasis shifted to molecules expressed on multiple cell types within and outside the haematopoietic lineages — not only because there are many more such molecules to define, but also because their functional importance is beginning to be appreciated. The interplay of lineage-specific molecules with molecules of broader distribution is evident in T-cell activation. The great specificity of T cells for particular foreign antigens is conferred by the T-cell receptor, a highly variable immunoglobulin-like heterodimer which associates with many other polypeptide chains to form the CD3 complex. Crosslinking of this receptor complex initiates intracellular signals including hydrolysis of phosphoinositol, Ca<sup>2+</sup> mobilization and protein kinase C activation.

An additional invariant T-cell-specific receptor, CD2 (T11), whose physiological function remains to be determined, activates a similar cascade of signals when perturbed by particular pairs of monoclonal antibodies. CD2 or CD3 generally fails fully to activate T cells by themselves; additional signals generated by other cell-surface molecules are necessary to initiate T-cell activation or to augment it. More than 15 surface molecules have been inferred to play such a role in altering T-cell activation; although many such molecules are T-cell specific (such as CD5, CD28), many others are not (such as CD43, CD45), including four newly implicated at this workshop (see table). Systematic approaches such as that described by S. Huet (Inst. Gustave-Roussy, Villejuif) promises to bring some order out of the chaos; she finds consistent patterns of complementation between particular pairs of incomplete signals mediated by CD2, CD3, CD5, CD27 and CD28.

Does this level of complexity reflect T-cell physiology, or elaborate artefact? Although the question remains open for

(CD58), ICAM-1 (CD54), and the transferrin receptor (CD71), it was a useful but unglamorous achievement to assign a standard nomenclature and to validate reference reagents. For others, such as the neural cell adhesion molecule N-CAM, ecto 5'-nucleotidase, decay-accelerating factor (DAF) and various molecules of the integrin family, it served notice that molecules being 'discovered' in one context are well known to those in other disciplines.

First, for example, CD29, used by T-cell immunologists as a marker of T-cell differentiation, is now understood to be the  $\beta$ -chain of the VLA family of integrin adhesion molecules. Second, CD56, known to immunologists as NKH1, a marker of natural killer cells, turns out to be an isoform of N-CAM. Third, many of the molecules are now being appreciated to be enzymes, including several different classes of peptidases: CD10 (ref. 5), CD13 (T. Look, St Jude Children's Research Hospital, Memphis) and CD26 (T. Mattern, Forschungs-Institut Borstel); ecto 5'-nucleotidase CD73 (L. Thompson, Scripps Clinic and Research Foundation, La Jolla); and the complement regulatory DAF protein (CD55). Thus, the unification

many of the molecules, biochemical mechanisms are being defined to account for regulatory effects of some of the best-studied molecules. CD5 mediates an increase in PIP2 precursor pool for phospholipase C (ref. 6), and CD28 stabilizes specific mRNA transcripts<sup>7</sup>. The 'non-linear' CD45 molecule, whose isoforms are proving to be extraordinary markers of lymphoid differentiation<sup>8</sup>, has recently been demonstrated to have an intracytoplasmic region which is a tyrosine phosphatase<sup>9</sup>. B. Schraven (Deutsches Krebsforschungszentrum, Heidelberg) reported that CD45 monoclonal antibody augments T-cell activation principally when activation occurs via the CD2 molecule, and that CD45 is physically associated with CD2, based on crosslinking studies. This finding, if confirmed, lends credibility to the model proposed by Ledbetter *et al.*<sup>10</sup> that CD45 regulates activation by association with and potentially by dephosphorylation of other receptor molecules. Together with the findings that CD4 and CD8 associate with p56 *lck* tyrosine kinase<sup>11,12</sup> (C.E. Rudd, Sidney Farber

Cancer Institute, Boston), there is potential for the complex regulation of T-cell activation by tyrosine phosphorylation and dephosphorylation. □

## SEMICONDUCTOR CLUSTERS

# Getting smaller by design

Michael Grätzel

SUBMICROSCOPIC clusters of semiconductor material are remarkable for the unusual properties they acquire through the quantum effects of their small scale. Two groups now report unusual synthetic routes by which cadmium sulphide clusters of specific sizes can be grown. Herron *et al.*<sup>1</sup> use zeolites, porous crystalline structures, as hosts to networks of CdS clusters which they term superclusters and which have additional quantum properties. And on page 596 of this issue<sup>2</sup>, Dameron *et al.* describe yeast cells that synthesize CdS crystallites as a means to

prevent cadmium poisoning in cadmium-bearing solutions.

Colloidal semiconductor particles 1-100 nm across are a new class of materials whose properties are intermediate between those of isolated molecules and solids. Apart from their potential application in the area of photocatalysis and solar-energy conversion<sup>3</sup>, they offer a convenient vehicle for studying the transition from the molecular to the bulk state. For example, several recent studies on semiconductor colloids have shown that their optical properties depend on their size —

the so-called quantum-size effect — and are significantly different from those of the macroscopic crystals.

Size quantization effects have been widely studied in the past for metal particles. In bulk metals, considered as the limit of an infinitely large system, there is a continuous spectrum of electronic states. In contrast, in very small particles, the energy levels are quantized, the spacing between adjacent states being of the order of  $E_F/N$ , where  $E_F$  is the Fermi energy — the characteristic energy of the most significant electrons in the system — and  $N$  is the number of atoms or

FIG. 2 a, Structure of zeolite Y and X, used in the study of Herron *et al.* b, Structure of the tetramer CdS(O) clusters located<sup>1</sup> within the zeolite/sodalite unit; (solid circles Cd, open circles S(O)).

molecules in one particle. Because  $E_F$  has a value of a few electron volts, the step size in a particle containing, say, a thousand atoms, is several millielectron volts. This quantization of states produces several anomalies in the properties of the particles, including their optical absorption, as was recognized 50 years ago.

For semiconductors, much of the earlier effort has concentrated on two-dimensional structures, such as quantum wells and superlattices. In thin films of semiconductors, a size quantization perpendicular to the film occurs. Three-dimensional systems displaying confinement effects, sometimes referred to as quantum dots, are the focus of more recent interest. Quantum-size effects in such semiconductor clusters were first observed by Berry in studies of silver halide crystals.

As the particle size is decreased, the band-edge absorption feature in the material's spectrum, corresponding to the minimum excitation, moves to shorter wavelengths (higher energies), a blueshift which is attributed to the local confinement of the electron-hole pairs (Fig. 1). This produces discrete electronic states in the valence and conduction band of the colloidal semiconductor and increases its effective band gap ( $E_g$ ). The blueshift in the absorption threshold is a consequence of the increased gap between the highest-occupied and lowest-unoccupied states. At the same time the oscillator strength of the optical transition is reduced and discrete absorption bands can appear in the spectrum. To a first approximation, the energy of the quantized levels is inversely proportional to the square of the particle diameter, because of the quantum effect

FIG. 1 Spatial electronic-state correlation diagram for bulk semiconductors and clusters. The conduction and valence bands (continuum states) of the bulk system become discrete levels because of the quantum-size effect in the cluster. Shallow and deep traps are associated with defects (impurities and lattice defects) in the crystal.

of confinement, with a correction to allow for the Coulomb interaction<sup>5</sup> between the electrons and holes. The luminescence of colloidal semiconductors is also strongly affected by particle size<sup>6</sup>. Typically, a broad emission is observed which blue-shifts with decreasing radius of the aggregate.

The synthesis of colloidal semiconductors is often carried out in solution by chemical precipitation. Because larger aggregates are thermodynamically more stable than smaller ones, it is necessary to arrest the growth process at a stage where the particles are still in the quantum-size domain. This is usually done by adding a protective agent, such as hexameta-phosphate, to the solution. However, this method gives a rather broad distribution of particle size, and tedious separation steps are required in order to obtain clusters with fairly uniform morphology.

Herron *et al.*<sup>1</sup> use an ion exchange procedure to incorporate Cd<sup>2+</sup> into the zeolite subsequently exposed to hydrogen sulphide gas to form the CdS microcrystals. An important finding from their detailed X-ray analysis concerns the location of the CdS clusters. At low concentrations, the Cd<sup>2+</sup> ions are preferentially adsorbed at the I' site of the zeolite Y (Fig. 2a), so that the clusters are located in the smaller sodalite cages and not, as one might expect, the supercages. The overall structure of the sodalite-cage-entrapped species is a distorted cube containing the tetramer (CdS<sub>4</sub>O)<sub>4</sub> (Fig. 2b). The unusual stability of these extremely small clusters is due to the coordination of the Cd<sup>2+</sup> ions with oxygen of the zeolite framework. These isolated CdS clusters are distinguished by their unique optical properties which deviate greatly from those of bulk CdS. Thus, the absorption threshold in their spectrum is around 350 nm, compared to 540 nm for bulk CdS. The absence of any luminescence emission, even at temperatures down to 4 K, is also conspicuous as large CdS particles show intense emission under similar conditions.

These optical properties undergo drastic changes at higher CdS loadings for which adjacent sodalite cages become occupied by the clusters. The absorption threshold shifts to 420 nm and an exciton-like feature (bound electron-hole 'atom') evolves at 350 nm. Strong emission appears owing to charge-carrier recombination on vacancies and lattice imperfections. These phenomena are ascribed to the formation of CdS 'superclusters' by a percolative process involving aggregation of the tetramers through the double six-rings linking the sodalite moieties. The novel feature of the superclusters is that every CdS molecule in the aggregate is on the surface and that strong coupling with the host lattice occurs through the interaction between Cd and the framework oxygen. This explains the unique optical

## Knotty problems in cosmology

NUMERICAL studies of the gravitational interaction of collections of point masses have been an important tool in 'experimental' cosmology for some 20 years — such interactions underlie the structure of the Universe at all scales. But many computational difficulties remain. To simulate a respectable fraction of the Universe with a limited number of particles, each particle must represent the mass of many galaxies, but now that observational cosmologists are beginning to map complete galaxy distributions throughout large regions of the Universe, the simulators can keep up their side of the work only by following their models at the level of individual galaxies. This means using enormous numbers of particles, which demands huge allotments of computing time.

A common compromise has been to put in large particle numbers, but then to approximate the behaviour of dense regions, as they form, with some kind of fluid mechanical treatment. But S. F. Shandarin (Institute of Physical Problems, Moscow) and A. Melott, working together at the University of Kansas, have returned to the simple but accurate device of calculating individual trajectories for each of 512 × 512 particles on a two-dimensional grid of comparable spatial resolution. Their technique demands too much computing power to achieve useful results in three dimensions, but reveals details which, were fewer particles used, would be invisible.

The scale of the simulations is arbitrary,

but features apparent in the figure resemble structures observed at the scale of superclusters of galaxies. The figure, a detail from one simulation, is colour coded (from red to violet) for the logarithm of the density. The darker regions could correspond to filaments of galaxies

and the intervening patches, 'voids'.

The large structures generally agree with those predicted in catastrophe theory and Zel'dovich's 'pancake' model, but the small-scale structure (such as the voids inside the filaments) is new. Of immediate interest is the suggestion that the small and large structures can be aligned over widely differing length scales. No detailed survey has yet found a scale beyond which the distribution settles to some uniform average. On all dimensions, something seems to be going on, and direct simulations such as these are needed to investigate the controlling influences. David Lindley

properties of these composites. It is noteworthy that CdS clusters in zeolite are distinguished from conventional colloids also by their selective intervention in photocatalytic processes<sup>7</sup>.

Dameron *et al.* describe in this issue<sup>2</sup> the biosynthesis of quantum-sized CdS crystallites in the yeast cells *Candida glabrata* and *Schizosaccharomyces pombe*. When exposed to cadmium ions, these cells respond with the synthesis of  $\gamma$ -glutamyl peptides, ( $\gamma$ -Glu-Cys)<sub>n</sub>-Gly and an enhancement of sulphide production. As a result, small crystallites of CdS are produced inside the cells. Surprisingly, the colloids crystallize in the rock-salt structure instead of the hexagonal configuration which is the thermodynamically stable form of CdS. The role of the peptide is that of a protective agent: the cysteinyl thiolates in the peptides are surface ligands to the core of around 85 CdS units. In this way, the organism controls particle

nucleation and growth yielding uniformly sized CdS particles of approximately 20 Å diameter. Not unexpectedly, the optical absorption of these aggregates reveals pronounced quantum-size effects as in the case of the zeolite contained CdS clusters. The findings of Dameron *et al.* provide a first example for the biosynthesis of quantum-sized semiconductor crystallites constituting a unique metabolic route for the detoxification of Cd<sup>2+</sup>-infected living cells. □

# Pathogenesis by antisense

Bob Symons

THE first determination of a nucleotide sequence of a 7S RNA species in plants is reported in a recent issue of the *EMBO Journal* by Heinz Sanger and colleagues<sup>1</sup>. This 7S RNA, isolated from tomato leaf tissue, is very similar to the known sequence of 7SL RNA from mammals, which prompts Sanger and colleagues to suggest that the two RNAs, both 299 nucleotides long, have similar functions.

Mammalian 7SL RNA, in combination with six proteins, forms the signal-recognition particle (SRP) responsible for protein translocation after synthesis<sup>2</sup>. In their new work, Haas, Sanger and colleagues produce a computer-generated model of the secondary structure of the tomato 7S RNA and report that its two-dimensional structure is also very similar to that of the mammalian species.

The more intriguing and unexpected aspect of the sequence and structural analysis of the tomato 7S RNA is the suggestion<sup>1</sup> that the pathogenic effects which viroids can cause in plants on infection are a consequence of the formation of a complementary hybrid between the viroid and 7S RNA. Viroids are the smallest infectious agents known<sup>3</sup>, consisting of circular, single-stranded RNA molecules which vary in length from 246 to 375 nucleotides. About 15 have been described so far, and most are pathogens that significantly affect agriculture. Many have a wide host range, infecting higher plant species, whereas others are restricted to a single family. Symptoms of infection vary

widely but the most common are dwarfing of the whole plant, curling downwards of the leaves (epinasty), and the appearance of yellow blotches on the leaves in certain hosts.

There is hardly any information as to how these intriguing agents exert their effects. One important aspect is the comparatively long time it takes for viroids to

plementary sequences in the tomato 7S RNA (see figure). The pathogenic effects of PSTV could be mediated by the formation of a 7S RNA–PSTV hybrid *in vivo* that would interfere with the normal role of 7S RNA in protein translocation across membranes. As the authors point out, viroid infection can lead to abnormal formation of cellular membranes.

Such hybrid formation would presumably need to occur in the nucleus during RNA synthesis. Although 7S RNA synthesis in tomato is likely to involve DNA-dependent RNA polymerase III, by

Possible base pairing between contiguous regions of tomato 7S RNA and of PSTV as predicted by Haas *et al.*<sup>1</sup>. Included also are possible base-paired regions in five other viroids; sequences are from refs 8, 12. Regions of three or more possible base pairs, which could theoretically form stable hybrids, are labelled A to E. There is reasonable conservation of the potential to form 7S RNA–viroid hybrids for the five boxed regions with significant variation in boxes B and C. Residue numbers given for the 5' and 3'-terminal nucleotides. G–C base pair taken as equivalent to a G–U base pair. Horizontal bars, spacings to allow maximum base pairing. CEV, citrus exocortis viroid; CSV, chrysanthemum stunt viroid; CPFV, cucumber pale fruit viroid; TASV, tomato apical stunt viroid; TPMV, tomato plant macho viroid.

produce phenotypic effects after infection, from about 2 weeks to more than 2 years. By contrast, plant viruses usually induce obvious symptoms in a few days. One of the most dramatic and damaging viroids is also the smallest: coconut cadang cadang viroid is only 246 nucleotides long, and yet it can kill coconut palms 10 to 20 metres high<sup>4</sup>. Expression of symptoms requires 2 years or more after infection, and is followed by certain death of palm trees within 5 years. This viroid is found only in the Philippines, where it destroys about 300,000 palms per year<sup>4</sup>.

Because there is no evidence that viroids can encode proteins, expression of symptoms must occur via the specific interaction of the sequence and/or tertiary structure of the viroid with one or more host components. It has been suggested by Solymosy and his colleagues<sup>5</sup> that viroids exert their pathogenic effects by interfering with the normal processing of pre-ribosomal RNA in plant nucleoli. However, the new model of Haas *et al.*<sup>1</sup> that pathogenicity results in hybrid formation between plant 7S RNA and the viroid, offers opportunities for more specific experimental testing.

In their comparative analysis, Haas *et al.* use the sequence of potato spindle tuber viroid (PSTV), which contains 359 nucleotides, as this viroid multiplies readily in tomato plants and produces characteristic symptoms of dwarfing and epinasty. They find five contiguous regions in this viroid which could theoretically form stable hybrids with com-

analogy with its mammalian counterpart, the RNA polymerase(s) responsible for PSTV synthesis have yet to be characterized. This viroid is known to accumulate in the nucleoli of tomato cells<sup>6</sup>, but its site of synthesis is unknown.

Direct support for the proposed model would be provided by the isolation from PSTV-infected tomato plants of stable 7S RNA–PSTV hybrids and the characterization of the base-paired regions. This would be very difficult to achieve experimentally, but supporting indirect evidence can be obtained in other ways. Haas *et al.* find that similar hybrid complexes can be formed between the tomato 7S RNA and four other viroids which infect tomato plants<sup>7</sup>: citrus exocortis viroid; chrysanthemum stunt viroid; tomato apical stunt viroid; and tomato plant macho viroid. The extra comparative data for these four viroids as well as for cucumber pale fruit viroid, which also infects tomato and produces symptoms<sup>8</sup>, are shown in the figure.

The formation and stability of 7S–viroid hybrids can readily be tested *in vitro* by hybridization of RNA transcripts, prepared from complementary DNA clones encoding tomato 7S RNA, with purified viroids. The melting profiles of such hybrids and the determination of the exact regions of hybrid formation in each of the RNA species would provide information on the ability of such hybrids to form. There may be surprises, as two-dimensional modelling cannot take into account the stability provided to an RNA–RNA

## 100 years ago

### THE MANATEE

THE Zoological Society have added to their living collection in the Regent's Park a young specimen of the Manatee (*Manatus americanus*), which those who wish to have an opportunity of inspecting an extremely curious form of Mammalian life should take an early opportunity of visiting. The Manatees belong to the order *Sirenia*, and are sometimes called "herbivorous Cetaceans," although it is very doubtful whether they have any near relationship to the true Whales or order Cetacea. These creatures were abundant in former geological epochs, but since the extermination of the *Rhytina*, or Steller's Sea-cow, at the latter part of the last century, have only two representatives still living, viz. the Manatee of America and Africa, and the Dugong of the Indian Ocean.

From *Nature* 39, 585; 18 April 1889.

hybrid by tertiary interactions. A good example of this is the very high stability of an *in vitro* hybrid formed between the 335-nucleotide linear satellite RNA of cucumber mosaic virus and part of the coat-protein gene encoding the viral RNA. Evidence indicated that the hybrid was formed by interaction between two short, separate blocks of nucleotides in the satellite RNA with two adjacent blocks in the coat-protein gene to produce a very stable pseudo-knot structure<sup>9</sup>.

Another indirect approach is to determine the sequence of 7S RNAs in other plant species where PSTV replicates and produces symptoms, and to check for the conservation of the blocks of nucleotides involved in the putative 7S RNA-PSTV hybrids. The best place to start would be with 7S RNA from two well-separated plant families, for example, another species in the family Solanaceae other than tomato, and two species from

the family Compositae which are often used for viroid replication — chrysanthemum sp. and *Gynura aurantiaca*. This approach could obviously be extended to the use of other viroids, with further fine tuning being applied through the use of different strains of the same viroid, such as PSTV or citrus exocortis viroid, where minor changes in sequence between strains can have a marked effect on the severity of symptoms in infected plants<sup>10,11</sup>.

Overall, the results of such various experiments could provide support for the model of 7S RNA-viroid interaction as the primary molecular event leading to the phenotypic disease symptoms, or require its significant modification. Whatever the outcome, the new data<sup>1</sup> make an important contribution to the unravelling of how small viroids exert their often dramatic effects. □

## GEOCHRONOLOGY

# ESR dating for the early Earth

Rainer Grun

PARAMAGNETIC centres in crystals, revealed by electron spin resonance, are used by earth scientists and archaeologists for dating samples, but because of their short mean life, the technique is restricted to the Quaternary era — the past 1.6 million years, a mere flash in geological history. Odom and Rink<sup>1</sup> now show that two such defects in quartz can last for at least 1.5 thousand million years. Quartz being the most abundant mineral in the Earth's crust, this study lays the foundation for an exciting new geochronometer that can be used to date numerous types of geological features over nearly the whole history of the Earth.

Electron spin resonance (ESR) spectroscopy allows the detection of paramagnetic centres in crystals, many of which are created by ionizing radiation. This effect can be used in dating studies: the mineral acts as dosimeter which records all the radioactivity of the mineral itself and its environment. The number of centres of any particular paramagnetic type is proportional to the accumulated radiation dose to which the sample has been exposed since it was last 'reset'. If one can reconstruct the dose rate the sample has received, it is possible to calculate an age.

In practice the accumulated dose is determined by the additive-dose technique: aliquots of the sample are exposed to artificial  $\gamma$ -radiation so that the specific ESR signal increases. Extrapolation to zero-ESR intensity yields the accumulated dose at the intersection with the dose axis. The dose rate is deduced from the chemical analysis of radioactive elements in the sample and its environment with the influence of cosmic rays allowed for.

For a mineral to yield a date for an event in geological time, it must have been exposed to a process which deletes any previously stored ESR intensity. For

example, precipitation of the mineral resets the ESR clock so that speleothems, spring-deposited travertines, shells, corals or teeth can be dated. The germanium centre in quartz is bleached by sunlight, allowing the dating of dune sediments and, eventually, loess. Resetting by heating can be exploited for the dating of volcanic minerals or heated archaeological flints. And lastly, the shear stress in fault zones resets several paramagnetic centres in quartz.

As can be seen from the range of events which can be dated, ESR has a large potential for geology and archaeology. It has been applied systematically as a dating technique since 1975 when Ikeya<sup>2</sup> dated a stalactite from Akiyoshi cave in Japan. (Owing to the rapid development of the technique, the only extensive English review<sup>3</sup> is already slightly out of date and other reviews<sup>4,5</sup> have not yet been published in English.) However, when ESR is applied as a dating method as described above, the upper dating limit is set by the thermal stability of the paramagnetic centres, which persist for durations of  $10^5$ – $10^7$  years. This has restricted ESR dating mainly to the Quaternary period.

Odom and Rink now investigate two ESR centres which can be attributed to Schottky-Frenkel defects in the crystal lattice of quartz. These are created by elastic collisions of recoiling  $\alpha$ -emitting nuclei with silicon and oxygen atoms. One centre is a peroxy radical, which cannot be enhanced by artificial  $\gamma$ -irradiation, the other is the precursor to the 'E' centre, which is a  $\text{SiO}_2^+$  centre. The plot of the relative ESR intensity of these two centres versus the known age of the granites from which the quartz was separated (see figure) shows a clear relationship between these two parameters. This opens the possibility of dating quartz over nearly the whole history of the Earth.

Nevertheless, as the authors point out, several basic questions need to be thoroughly investigated. First, a precise measurement of the number of Schottky-Frenkel defects is still hard to obtain: the characteristic ESR lines are often very small and close to the background signal. Extreme spectrum accumulation or

Plot of relative ESR intensity of the peroxy-radical centre (left) and the E' centre (right) versus the known age of the quartz (after Odom & Rink<sup>1</sup>).

specifically designed microwave cavities may solve this problem. Second, the precise quantities of  $\alpha$ -particle emitting isotopes must be determined. These isotopes belong to the uranium and thorium decay chains. However, their concentration in quartz lies normally in the parts-per-billion range which is difficult to measure. The authors suggest comparing the natural ESR signal from quartz of known age with neutron-induced signals, but this approach seems unsuitable for investigation of samples of unknown age.

Third, as already pointed out by Kislyakov *et al.*<sup>6</sup>, the number of E'-centres per unit of radioactive elements may vary depending on the variety of the quartz under investigation. This dependency and also saturation effects would have to be studied. Lastly, the defects seem to be thermally stable for around  $10^9$  years. This should be confirmed, because the concentration of centres reaches a steady state in samples older than the mean life of the defects. It was previously reported<sup>7</sup> that the point defects which

lead to the E' paramagnetic centre have a mean life in the range of  $10^8$  years (at  $20^\circ\text{C}$ ).

Although the investigation of these problems is not a trivial task, it seems now very likely that in the near future, ESR dating can be extended from the Quaternary to the whole geological timescale and that ESR dating will be applied to many chronological problems which could not be solved with established dating techniques. □

## CONSERVATION BIOLOGY

# Nine hundred kiwis and a dog

Jared M. Diamond

INTRODUCED predators are thought to be a leading cause of the extinction of island species. Yet the evidence for this is inferential in many cases, with few or no direct observations of predation. It remains baffling how victim species can disappear so quickly, and how a predator species can eradicate a victim species completely before its own numbers collapse. Thus, the recently documented collision between one dog and a population of 900 kiwis is likely to become cited as a classic case study in conservation biology (Taborsky, M. *Notornis* **35**, 197–202; 1988).

New Zealand has lost a high proportion of its native bird species in the few centuries since Europeans arrived. Introduced weasels, cats and dogs may be responsible, but firm proof is lacking even for well-known endangered species such as the kiwi, New Zealand's national bird. The three species of kiwi are all large, flightless birds confined to New Zealand and adjacent islands, but it is not known why one (the little spotted kiwi) has vanished from the New Zealand mainland.

Until recently, the 11-square-mile Waitangi State Forest supported the largest-known and counted population of brown kiwis (*Apteryx australis*). Between June and October 1987, biologists marked some individuals of this population and followed them using radio transmitters.

On 24 August 1987, a large female kiwi was found freshly dead. Over the next 6 weeks more fresh carcasses were located, usually buried under leaves and soil. Of the 23 marked birds, 13 died during this period and were discovered through their radio transmitters. Despite the very low chances of detecting a buried kiwi carcass without the help of a transmitter, 10 carcasses of unmarked individuals were

The brown kiwi is defenceless against introduced predators.

also discovered. By the end of September many fewer kiwi calls were being heard, and a dog trained to locate kiwis (but not kill them) could find none.

Tooth marks and footprints showed that all the dead kiwis had been killed by a dog, which had buried but not eaten them. All parts of Waitangi Forest that were searched yielded dead kiwis, dead possums, dog footprints, or dog faeces

containing kiwi feathers or possum remains. The footprints and faeces all appeared to be from the same dog. On 30 September, a German shepherd dog was found in the forest and shot. Thereafter no marked kiwis disappeared and no further dog signs were found.

How many kiwis did the dog kill? The 13 deaths among the 23 marked birds would mean 500 deaths in the whole population of 900, if marked and unmarked birds were at equal risk. In fact, the population may have suffered greater losses, because the proportion of marked birds killed was nearly twice as high outside than inside the main study of 0.5 square miles, where the biologists' presence may have deterred the dog. Five hundred killings in 6 weeks would mean about 12 kiwis killed per night. That kill rate may at first appear unbelievably large, but kiwis have a very strong distinctive smell, forage and call noisily, so are particularly vulnerable to predators.

The Waitangi incident illustrates many points relevant to the extermination of island species by introduced predators. Kiwis evolved in the absence of mammalian predators and are entirely defenceless against dogs. They breed so slowly that the Waitangi population will require an estimated 8–20 years to recover even if no such incident recurs. It took just one dog to halve the size of the largest-counted brown kiwi population in 6 weeks, yet the cause of that decline would have remained unknown but for the coincidence that some of the buried carcasses had been radio-tagged. Hence it becomes less surprising that New Zealand's abundant feral cats and weasels could have exterminated other native species without being identified as the culprits.

The kiwi incident also illuminates the paradox of how a predator could exterminate its prey without exterminating itself first. Like most other introduced pests, dogs are 'switching predators' for which kiwis are just one of several potential prey species: this particular dog did not even eat the kiwis that it killed.

Finally, the Waitangi incident emphasizes the importance of control of introduced pests. Responsibility for the forest was recently transferred from the New Zealand Forest Service to a timber corporation, which abandoned the previous policy of keeping the forest free of dogs. As Taborsky says, "The disappearance of kiwis from other populated parts of New Zealand during the last decades underlines the general importance of the issue to the protection and management of kiwis". □

## NITROGEN FIXATION

# New route to a sticky subject

Sharon R. Long and David W. Ehrhardt

RECOGNITION between cells or organisms is an essential component of pathogenesis, of defence and of development itself. All three processes are involved in the nitrogen-fixing symbiosis between *Rhizobium* bacteria and host plants. Specificity is one of the most prominent features of symbiotic nodule development: particular bacteria will invade and form nodules only on some host plants and not others. Because it seemed logical that surface interactions might be involved, much attention has been given to the notion that plant proteins such as lectins might specifically bind to bacteria surface determinants<sup>1</sup>. It has been a difficult and so far elusive task to identify the bacterial surface components that might be responsible for the host-specific interaction of *Rhizobium* with plants. Now, a new study reported by Díaz *et al.* on page 579 of this issue<sup>2</sup> uses a fresh route to test specificity determinants: the genetic alteration of the composition of the root.

The authors introduce a lectin gene from pea (*Pisum sativum*) into the genome of clover (*Trifolium repens*) roots via *Agrobacterium rhizogenes* transformation. The transgenic roots still nodulate with the clover symbiont, *Rhizobium leguminosarum* biovar *trifolii*, but they display an elevated frequency of nodule formation with *R. leguminosarum* biovar *viciae*, the pea symbiont.

Host range in the *Rhizobium*-legume system exists at several levels. First, the Rhizobiaceae (*Rhizobium*, *Bradyrhizobium* and *Azorhizobium*) generally infect only plants in one plant family, the Leguminosae. Second, there are 'cross-inoculation groups' of *Rhizobium* and plants, defined by sets of bacterial strains (formerly considered species) which typically nodulate the several members of a corresponding plant set. *R.l.* biovar *viciae*, for example, nodulates peas, vetch and a few other plants, but not clover. (The study by Díaz *et al.* concerns the basis for this cross-inoculation group level of specificity.) Finally, there is a fine structure to nodulation host range, such that certain strains of a bacterial species might not nodulate all genotypes of their usual host; this behaviour is sometimes conditioned by single genes in the bacterium and the host plant.

A successful combination of host and bacteria requires compatibility at many different stages in the symbiosis, from the initial interaction to successful differentiation to nitrogen fixation<sup>3-5</sup>. The success of early *Rhizobium*-host interactions is characterized by the curly deformation of the plant's epidermal root hairs, the invasion of these root hairs by bacteria

within an infection thread (see Fig. 1) and the initiation of new cell divisions within the plant root, which eventually result in the outgrowth of a nodule. Because host specificity is often limited at these early steps, they have received most attention.

Bacteria and plants that are not in the correct cross-inoculation groups — such as *R.l. viciae* placed on clover plants — do not get as far as the infected root hair shown in Fig. 1; so there must be some barrier early in the interaction. Attachment of bacteria to the root surface might be an essential step, and it has been proposed that lectins could mediate this interaction<sup>6</sup>. Attachment, however, is hard to quantify, because the highly charged cell wall that surrounds all plant cells gives a substantial background to measurements of bacterial binding. Binding assays carried out using microscope observation have not been uniformly correlated with quantitative measurements using radioactively labelled cells<sup>1</sup>. The strength of the study by Díaz *et al.*<sup>2</sup> is that such a problematic assay is not involved; a discrete change was made in host cell determinants using the plant's own cellular machinery, and this change

FIG. 1 Successful infection of *Rhizobium* into many legumes is characterized by formation of an infection thread in an epidermal cell. Normally, straight root hairs grow into a curled form and are invaded by *Rhizobium* of the correct cross-inoculation group. No defence reaction occurs in the root-hair cell; instead, the bacteria penetrate to the main body of the root within the actively elongating, branching infection thread whose wall is synthesized by the plant cell. The dynamic process must involve highly localized and directed bacterial functions, and a complex cell-wall growth response in the plant. Genetic studies on *Rhizobium* indicate that specificity determinants are an intrinsic part of the mechanisms directing these active plant responses.

leads to a marked alteration in nodulation phenotype. It is noteworthy, however, that although the transgenic clover roots studied here gain significant nodulation functions, the gain of function is not complete. Nodules form infrequently, and are often abnormal in morphology, suggesting that although the pea lectin represents one primary limitation or screen for symbiotic partners, there are others.

That the determination of host range involves multiple components and steps is also now indicated by studies of bacterial symbiotic genes. Numerous bacterial genes have been identified as affecting nodule formation, and these fall into several categories<sup>3-5</sup>. Some, for example *nodABC*, are highly conserved, both in DNA sequence and in function, and seem to be central to the stimulation of nodule formation on all plants. Another type, such as *nodH* in the alfalfa symbiont *R. meliloti*<sup>7</sup>, are unique to bacteria of a particular nodulation specificity. Other genes, including *nodFE*, are conserved among different *Rhizobium* strains in terms of their nucleotide sequences, but they nevertheless seem to affect host range. The *nodD* regulatory genes even seem to combine universality and host selectivity: although the ultimate regulatory effect of *nodD* — the activation of transcription of nodulation genes — is parallel in various *Rhizobium* strains, the spectrum of plant-derived inducer molecules which stimulate this effect varies for *nodD* genes derived from different *Rhizobium* species<sup>8</sup>.

The genes known to be present in *R.l. trifolii* and *R.l. viciae* are remarkably similar (see Fig. 2), yet the bacteria nodulate different hosts<sup>9</sup>. Experiments to analyse this have revealed unexpected properties of some host-range genes. *R. l. trifolii* containing a mutated *nodF* or *nodE* gene is converted to behave more like *R.l. viciae*, for example — it broadens its host range to interact with pea, and becomes less efficient on its original host, clover<sup>4</sup>. In general, individual host-specific nodulation genes seem to affect efficiency or frequency, but do not seem to be absolutely required. Thus, whereas host range itself is a strict phenotype, mutation of individual bacterial genes controlling host range gives leaky phenotypes. Such observations, together with studies in several laboratories of double mutants, have led to the widely discussed proposal that the host-range phenotype results from the additive effects of multiple mechanisms, which may exist in differing combinations among various host-microbe pairs, not in mutually exclusive sets. The picture that has emerged from genetic studies, then, is that host range is not controlled by a single locus, in which one key is matched to a lock, but is more likely to be combinatorial.

Díaz *et al.*<sup>2</sup> demonstrate that a lectin can

FIG. 2 Map of nodulation genes in two biovars of *Rhizobium leguminosarum*, *a*, by *viciae*, which infects pea, vetch, lentil and related plants; and *b*, by *trifolii*, which infects clovers. The genes have been established by transposon mutagenesis, sequencing and some protein product analysis<sup>4,5</sup>. Asterisks indicate positions in which various researchers believe further genes will soon be defined. Those genes designated 'common' are functionally interchangeable without an effect on host range; in particular, *nodABC* seem to stimulate host cell divisions and nodule formation, and are also required for root-hair deformation<sup>3</sup>. These common genes do not function well without accompanying host-specific nodulation genes, such as *nodFE*, which appear critical for proper root-hair curling and infection<sup>4,5</sup>. An example of a fine-structure host range gene is *nodX*, found in some but not all *R. l. viciae*; without *nodX*, *R. l. viciae* strains are restricted to nodulating only certain genotypes of pea<sup>5</sup>.

Host plant specific	"Common"	Host genotype specific
* NM L EF D ABCIJ X		<i>R. l. viciae</i>
* NM L* EF D ABCIJ *		<i>R. l. trifolii</i>

be important in this process. Whether changing the lectins expressed in other host plants can similarly affect infection by *Rhizobium* remains to be seen. The two bacteria which nodulate pea versus clover are more closely related than most pairs of *Rhizobium*. Those which are less closely related may have more dramatic limitations to nodulation on their heterologous hosts. It would not be surprising if different host/symbiont combinations in varying isolation evolved exclusivity and compatibility to different degrees and along slightly different avenues.

The molecular role of any receptor, of course, remains difficult to study until it is known to what it binds. This remains a sticky point in research on *Rhizobium*-legume systems. If plant lectins are receptors for bacterial carbohydrates, it may be that the relevant sugars are sweetening up a surface component not identified to date. For example, researchers working on the genes which control several types of extracellular polysaccharides in *Rhizobium* find that eliminating or altering surface components such as the acidic exopolysaccharide<sup>9</sup> or the lipopolysaccharide<sup>10</sup> prevents successful invasion, but allows formation of uninfected nodules in a correct host-specific manner. Therefore, these carbohydrates do not seem to correlate with host range, although it remains possible that there is redundant information in several surface determinants. Identification of specific bacterial molecules interacting with host components will be essential before the issue of how lectins affect the symbiosis is resolved.

The availability of transgenic roots with altered nodulation properties will allow genetically tailored microbes and plants to be paired with each other for specific mechanistic tests. It is of interest, for example, to test bacteria altered in known nodulation genes on transgenic roots with host-range changes that are complementary. Expression of lectin genes in heterologous backgrounds may help to determine exactly where the lectin is expressed and localized in transgenic plants, for example, and under what circumstances its functional properties are preserved. Previous studies on pea have shown that lectin binding of *R. l. viciae* can be assayed only under manganese limitation of the

bacteria<sup>11</sup>: do the transgenic clover/pea lectin roots bind their new *R. l. viciae* symbionts in this manner?

Finally, how are host-range functions coupled with the action of the common nodulation genes? Genes such as *nodABC* drive the plant to begin cell divisions, and are also required for root hair curling and invasion, but they do not have a productive effect on a host plant unless they are accompanied by the proper host range genes. Bacteria with normal *nodABC* genes, but lacking a host-range gene, for example, often cause the plant to exhibit incomplete or atypical root-hair deformations. If host-range genes are additive in effect, then perhaps they act by modifying a central function or functions provided by the common *nod* genes, increasing their efficiency. There is new experimental support for this model<sup>12</sup>. In addition, host-range genes might also act by directing the location and timing of the action of *Rhizobium* on its target; by providing access for a molecular signal or a cell to a site of action; by actively modifying the bacteria's immediate molecular environment within the plant cell wall or membrane; by preventing a host defensive reaction; or by some combination of these. Given that the transfer of the pea lectin can change the responsiveness of clover roots to *Rhizobium*, it may be possible to test whether the function of this lectin is simply in attachment, or whether it acts through more complicated, possibly more active, mechanisms. □

## Long sight

LAST week Daedalus devised his 'Space Spider'. This ingenious spacecraft propels itself by melt-spinning and ejecting a fine optic fibre. Cunningly, the fibre is made of a lasing glass, excited by the sunlight of space. It amplifies light pulses as they traverse it, and forms an active optical communication link back to Earth.

Daedalus now reckons that his space-borne light guide should be a powerful research tool in its own right. Thus it could form an astronomical interferometer of unprecedented resolution. The light from a stellar source spreads out in a wide wavefront. When two separate sections of the wavefront are recombined, traditionally by means of a pair of mirrors, the resulting interference pattern can be decoded into an image of the source. It is hard to give such an interferometer a mirror separation greater than about ten metres, so it can only just resolve the diameters of the nearer, bigger stars. But an active space-borne optic fibre could recombine sections of wavefront millions of kilometres apart.

Daedalus envisages a command spacecraft with two fibres extending out from it, their far ends anchored to two observation platforms. Each platform would use a stabilized telescope to image light from the chosen astronomical object onto the end of its fibre. The light from the two telescopes would flow down the fibres and interfere at the central command craft. If the orbits of the telescopes were chosen to vary the distance and angle between them, the changing interferogram would slowly accumulate an aperture-synthesized image of the object. A source a thousand light years away could be resolved to a few kilometres!

More boldly still, Daedalus wants to use his space-borne fibre to detect gravity waves. These energetic but elusive phenomena are emitted by massive moving objects like big, short-period binaries, collapsing neutron stars, supernovae, and black holes in the act of swallowing a star. Even gravity waves from the early days of the Universe may still be echoing around. They should shake an optical interferometer as they pass through it. Terrestrial interferometers have so far failed to detect them: but Daedalus's space-borne fibre interferometer should be mightily more sensitive. Its optical length would only change in second order, but the shift of the interference pattern should still be very clear. Gravity waves would also deform the fibre slightly as they passed through it. The birefringence thus induced would be tiny indeed — but a light pulse traversing a million kilometres of such a fibre should suffer detectable changes of polarization. Much exciting astrophysical mayhem, undetectable by optical or radio emission, should thus be revealed in all its gravity.

David Jones

# Leucine zipper motif extends

SIR—Landschulz *et al.*<sup>1</sup> have recently proposed that the 'leucine zipper' is characteristic of a new category of DNA-binding proteins. In this hypothetical structure the side-chains extending from an heptadic repeat of leucine residues over a distance covering (at least) eight turns of an  $\alpha$ -helix, interdigitate with those on a similar helix of a second polypeptide, thus facilitating dimerization. The Fos and Jun transforming proteins both contain such a motif and Landschulz *et al.* speculate that it plays a role in the heterotypic complex these proteins can form<sup>1</sup>.

We report the presence of the same motif in proteins that are not DNA-binding. As shown in the figure, the fusion (F) glycoproteins of paramyxoviruses each have a leucine-zipper motif, which is in an  $\alpha$ -helical structure situated 4–11

amino acids from the transmembrane area. In some cases, isoleucine is substituted for one of the leucines, but Kouzarides and Ziff<sup>2</sup> have shown that this does not affect the interaction of Fos and Jun. Further analysis of the proposed structure reveals that at position 4 alongside the leucine, there is always a small uncharged amino acid, whereas charged amino acids are distributed in the other five positions.

Studies with influenza haemagglutinin<sup>3</sup> and the glycoprotein of vesicular stomatitis virus<sup>4</sup> have shown that after their synthesis in the endoplasmic reticulum, these glycoproteins must oligomerize in order to be transported to the cell surface via the Golgi complex. Conceivably, the same is

true for the F glycoproteins of paramyxoviruses, in which case dimer and tetramer formation may be mediated by the leucine zippers. The F glycoprotein of Sendai virus is a tetramer when isolated under non-denaturing conditions<sup>5</sup>.

## Stereo problem

SIR—I have frequently suffered frustration because of the reversed depth and handedness of stereo-images when viewed directly from the printed page, especially when other clues such as the size of components or their shading are adjusted to give parallel depth information. Like most people, I view such images with crossed visual axes. The diagram in Vance Tucker's letter (*Nature* 337, 605; 1989) suggests a simple solution.

If one member of a stereo-pair were to be flanked on either side by identical copies of the other stereo-pair, as in Tucker's diagram, then a reader could see the correct depth and handedness by looking at, say, the left pair with uncrossed visual axes and at the right pair with crossed axes. The same procedure could also be used with projected images from slides, films or overhead projectors, although given that many individuals who view close stereo-pairs with uncrossed axes view distant pairs by the crossed method, it would probably suffice to project only the 'crossed' arrangement. Unfortunately, in my experience it is more usual for the uncrossed images to be projected or printed (for example, the stereo-pairs on pages 618 and 619 of the same issue of *Nature*), causing confusion to most direct viewers.

## Stop taxonomists

SIR—Replying to complaints<sup>1</sup> about the number of changes in biological nomenclature, Hawksworth suggests<sup>2</sup> that "international peer reactions are the most likely prospect for restricting unwelcome changes...". Unfortunately, this restriction seems unlikely to happen if the peers are fellow taxonomists.

One difficulty stems from some of the general assumptions of taxonomists: even Hawksworth's distinguished predecessor, G.C. Ainsworth, held that more is better.

He wrote<sup>3</sup>: "the very welcome upward trend in the proportion of new combinations indicates that increasing attention is being paid to revision".

Biologists need good taxonomy, with each name unambiguous and reasonably constant. However, in their enthusiasm, taxonomists make frequent changes and revisions of these changes that cause confusion to other biologists who use the names. This is nothing new; it has been going on for years and it is time it stopped.

This conflict of interest between taxonomists, who want to change the names of organisms, and other biologists, who do not, could be resolved. Taxonomists could continue publishing their findings, as now, but international standing commissions could review these publications every few years and issue lists of official names. These names would hold until the next list was issued, so that names would be standardized over periods of several years.

## Carbonatite origin and diversity

SIR—A recent paper<sup>1</sup> and an accompanying News and Views article<sup>2</sup> explained the origin and diversity of carbonatites by production of primary carbonatite magma in the mantle, followed by fractional crystallization. Gittins<sup>2</sup> considers the experimentally produced carbonatite melt of ref. 1 to be particularly relevant to the problems of carbonatite magma genesis because it contains the oxides required to crystallize the silicate, phosphate and oxide minerals that are commonly associated with the carbonate minerals that form the majority<sup>3</sup> of carbonatite rocks.

In contrast, Gittins<sup>2</sup> asserts that the carbonate liquids produced by immiscibility in our experimental studies<sup>4,5</sup> are too poor in non-carbonate components to be considered relevant to natural systems. Twyman and Gittins<sup>6</sup> previously postulated a mildly alkalic olivine sövite as a suitable parent magma; the proposed composition of this magma is listed in the table, together with the carbonatite melt composition of ref. 1 and immiscible silicate/carbonate liquid pairs from refs 4 and 5 and our new work (in preparation).

Contrary to Gittins' statement, some of the carbonate liquids produced experimentally in ref. 4 contained significant amounts of non-carbonate components. Although the FeO and MgO contents of these carbonate liquids are quite low, this simply reflects the fact that the starting bulk composition was very poor in these

 (8) Conjugate silicate liquid to (4).  
 (9) Conjugate silicate liquid to (5).  
 (10) Conjugate silicate liquid to (6).

components. The distribution of elements between immiscible liquids is strongly affected by pressure, temperature and the bulk composition of the system<sup>4</sup>, with compositional effects being particularly important (see Fig. 6 of ref. 4). Kjarsgaard and Hamilton<sup>5</sup> used compositions containing only five components (SiO<sub>2</sub>-Al<sub>2</sub>O<sub>3</sub>-CaO-Na<sub>2</sub>O-CO<sub>2</sub>), so the immiscible carbonate liquids produced could not contain FeO, MgO, P, O<sub>2</sub> and the like. Gittins was correct to point out that these melts were poor in Si O<sub>2</sub> and Al<sub>2</sub>O<sub>3</sub> (see column 4 of the table), but again this could be the result of pressure, temperature and composition. Our more recent (unpublished) results show that the addition of TiO<sub>2</sub>, MgO, FeO, F and P<sub>2</sub>O<sub>5</sub> ensures that these components occur in the immiscible carbonate melt, and also that the addition of these components affects the partitioning of Al<sub>2</sub>O<sub>3</sub> and SiO<sub>2</sub> between immiscible melts such that the carbonate liquids contain noticeably higher contents of these two elements.

The table shows that we have produced, by immiscibility, carbonate liquids whose compositions compare favourably with those considered to be "realistic carbonatite parent magmas" by Gittins (compare columns 5 and 6 with columns 1 and 2). Furthermore, the conjugate alkali silicate liquids produced in these experiments (compare columns 9 and 10) have compositions that are suitable as parent magmas for the attendant alkali silicate rocks found in carbonatite complexes.

Gittins<sup>2</sup> suggests that the next step in testing the primary-melt model of ref. 1 is to examine rare-earth element concentrations. Hamilton *et al.*<sup>7</sup> have made this test for an immiscible silicate/carbonate system, using lavas from Oldoinyo Lengai as

starting materials. Rare-earth element concentrations for the Oldoinyo Lengai phonolite and natrocarbonatite<sup>8</sup> are used in ref. 7 to calculate a set of natural rock partition coefficients, and these compare very well with those derived from the experiments at 3 kbar and 1,050 °C.

Any debate on carbonatite magma genesis should include proper consideration of the viability of the immiscibility hypothesis. This process, in conjunction with fractionation, can convincingly account for both the major- and trace-element contents of carbonatites as well as the associated alkali silicate rocks.

Manchester M13 9PL, UK

GITTINS REPLIES—The proponents of liquid immiscibility as the explanation for carbonatite magmas consider the experimental demonstration that various carbonate and silicate liquids are immiscible up to at least 8 kbar pressure to be proof that the carbonate and silicate liquids separated from a common parent magma, whereas I maintain that one must demonstrate not only the existence of liquid immiscibility but also a derivative relationship. In my view this requires the formation of a single quenchable liquid from the two immiscible liquids. Such a liquid might be the hypothetical CO<sub>2</sub>-rich nephelinite (or phonolite) that is invoked by Le Bas<sup>9</sup>. If it exists in nature it should be possible to make it in the laboratory.

Until this is done we can only examine the natural rocks for evidence of a CO<sub>2</sub>-rich nephelinite that has fractionated to a stage just short of single-liquid instability,

and ascertain what sort of rock it is. We find no such rock — only simple olivine nephelinites and nephelinites.

The postulated parental magma of ref. 6 is not completely correct (for example, the P<sub>2</sub>O<sub>5</sub> content is too high) but it is a useful beginning. Some of Kjarsgaard and Hamilton's immiscible carbonate liquids are similar but they and the  $K_D$  values of the table are relevant to the problem only if carbonatite magma separates immiscibly from a silicate parent (which is not yet proved) and if the contents of rare earths and other elements such as Nb, P, Sr, Ba, F and Cl are sufficiently high in the parent silicate magma for partitioning to produce the characteristic carbonatite element concentrations. In saying that the next step in testing the primary melt model of ref. 1 would be to examine the rare-earth element concentrations, I was simply making the point in my News and Views article<sup>2</sup> that unless the liquid of ref. 1 contains the necessary major- and trace-element concentrations it is not a viable parental carbonatite magma. The fact that Hamilton *et al.* have successfully partitioned rare earths into a carbonate liquid at the expense of an immiscible silicate liquid is interesting, but irrelevant to evaluating ref. 1.

I might also point out that if the experiments in ref. 7 used only CO<sub>2</sub> as a transporting fluid they are of limited value because the mobility of CO<sub>2</sub> is restricted to a depth corresponding to 27 kbar, the pressure at which silicate carbonation reactions fix CO<sub>2</sub>. Something capable of transporting elements at greater depths is required, and our (unpublished) work suggests that fluorine plays a major part in this and in just about every other aspect of carbonate liquid systems.

Carbonate/silicate liquid immiscibility exists. But is it merely a physical property of silicate and carbonate magmas or does it control their genesis? Do these magmas separate as conjugate liquids from a single mantle-derived parent, or are they each the result of separate mantle-melting events? Is immiscibility a relatively late-stage, upper-crustal process of minor petrological significance, or the principal process by which carbonatite magma is generated?

## CURRENT ADVANCES IN IMMUNOLOGY

*Current Advances in Immunology* is one of twelve journals produced from the *Current Awareness in Biological Sciences* (CABS) Database. CABS provides the working biologist with a contents service which is fast, economical and easy to use. Specialised subject editors scan over 3500 international journals, classify the articles and add them to the database in a simple and user-friendly format, giving complete details of title, authors and authors' addresses, and bibliographic information.

- ☐ Clear format enabling speedy use
- ☐ Comprehensive coverage allowing user to make own judgements
- ☐ Unlimited cross-referencing
- ☐ Full address with each author making it easy to write for reprints
- ☐ Timesaving breakdown into detailed classification scheme
- ☐ Up-to-date — 4-6 weeks publication
- ☐ Also available online

Annual subscription, 12 issues, starting in any month  
**only £27.00 / US\$43.00 / DM80.00**

# In pursuit of the peculiar

P.V.E. McClintock

**Methodological Aspects of the Development of Low Temperature Physics 1881–1956: Concepts out of Context(s).** By Kostas Gavroglu and Yorgos Goudaroulis. *Kluwer Academic*: 1989. Pp. 178. Dfl.125, \$67, £36.

PROGRESS in science often arises through a fruitful interplay between experiment and theory. New experimental observations — made possible, perhaps, by some advance in instrumentation — may fail to agree in all respects with theories constructed to account for related phenomena; those theories then have to be modified, leading to fresh insights and, perhaps, to new predictions which can then in turn be tested. But what happens when the discrepancy between observation and expectation is so gross that the existing theoretical framework simply cannot, by any stretch of the imagination, be modified or extended to accommodate the new information? In their book, Gavroglu and Goudaroulis attempt to answer the question through an historical study of low-temperature physics.

Both of the authors are active in theoretical atomic and elementary particle physics. Given this background, it is interesting to note that, in seeking the “most peculiar” phenomena on which to base their study — admittedly a subjective judgement — they eventually “were amazed to realize that neither the phenomena of the very small nor those of the very large could compete with the phenomena of the very cold”.

The phenomena in question are superfluidity and superconductivity, and they certainly are peculiar. Each of them involves the onset of a form of frictionless flow below a critical temperature. In the case of helium, the liquid acquires the ability to flow easily through tiny orifices of vanishingly small dimensions or, even more astonishingly, to climb out of any open-topped vessel in which it is placed: in fact, it behaves as though its viscosity was zero, whence the appellation superfluidity. The frictionless flow of the electron gas in a superconducting metal, in many ways a similar phenomenon and equally unexpected at the time of its discovery, means that an electron current can flow forever around a closed loop of conductor without needing a driving voltage to maintain it; the technological implications of superconductivity, particularly if large current densities can be achieved at relatively high temperatures, have been well publicized in recent months.

In outline, the story of the discovery of superfluidity and superconductivity is a familiar one. It starts, in effect, with the liquefaction of helium — the last of the so-called permanent gases to succumb — by

Kamerlingh Onnes at Leiden in 1908. Once liquid helium was available for use as a cryogenic fluid, experiments went ahead on a wide range of materials at very low temperatures. In 1911, Onnes reported an exceptionally odd and, as it turned out, historic observation that the electrical resistance of mercury apparently fell abruptly to zero (that is, the

Kamerlingh Onnes — historic observation. (onset of superconductivity) as it was cooled through a transition temperature of about 4.2 K.

Although liquid helium continued to be used as a cryogen to cool a variety of experiments at Leiden and later at several other laboratories, and although many researchers were aware that it was an unusual liquid, its really remarkable property (of superfluidity) was not appreciated until surprisingly late, in 1938, with the famous Volume 141 of *Nature* in which workers in Cambridge, Moscow, Oxford and Kharkov reported almost simultaneously a whole range of phenomena leading in different ways to the same conclusion: that liquid helium below 2.17 K is a superfluid. The authors describe the history of these events in considerable detail,

mainly through reference to the literature, but also on the basis of their visits to Leiden and other centres of low-temperature research, and in the light of their discussions and correspondence with survivors from the latter part of the era in question, and with their collaborators and successors. They concentrate mainly on the period 1908–1956, but also provide valuable background on earlier years and an outline of developments after 1956.

The discovery of superconductivity certainly occurred “out of context”. It came while the quantum theory was in its infancy, before the development of quantum statistical mechanics, and it far preceded the advent of those theories of the solid state which were to be a prerequisite for its proper understanding. Superfluidity also arrived “out of context” but, coming more than a quarter of a century later, somewhat less so. The authors discuss in fascinating detail the twists and turns of the argument and the interplay between experiment and theory which led, in the end, to reasonably satisfactory understanding of the two phenomena by the mid-1950s. They could also have pointed out, however, that in the case of superconductivity, the resultant theory — the Bardeen–Cooper–Schrieffer (BCS) theory — was a good deal fuller, more fundamental and generally more satisfactory than that for helium (an uneasy co-existence of the early ideas of London, Tisza and Landau, together with the later unifying contributions of Feynman and others).

The approach taken by Gavroglu and Goudaroulis in analysing these events relies on their idea of “concepts out of context(s)” wherein a paradoxical situation is created by the initial attempts to describe a new phenomenon, precisely because it is incompatible with prevailing theory. The resolution of the paradox involves the development of a new theoretical framework, providing a context within which the phenomenon in question will be expected, rather than unexpected. Few scientists are likely to disagree with such an interpretation, which, stripped of the authors’ jargon, is a seemingly obvious one.

Gavroglu and Goudaroulis tell us a tale of considerable intrinsic interest involving technical ingenuity, astonishing discoveries, imagination, insight, bitter arguments between proponents of conflicting theories and, ultimately, triumph in terms of scientific understanding. The story is carefully told, with copious annotations and references to the original literature. There are some obvious lacunae, however, particularly in relation to historical perspectives on superfluid helium. For example, in the course of their description of the early controversy surrounding London’s seemingly outrageous suggestion that Bose–Einstein condensation (where, in

an ideal gas at a low enough temperature, particles 'condense' into the zero momentum ground state) might also occur in liquid helium, the authors do not mention that London was eventually proved correct by the neutron-scattering experiments of Eric Svensson and co-workers at Chalk River. Similarly, they provide an account of the Landau critical velocity paradox — Landau having predicted a critical velocity for the onset of frictional effects in superfluid helium that was several hundred times larger than the critical velocity actually observed in the early experiments — and of Feynman's resolution of the paradox in terms of dissipation through vortex production at lower velocities. But they forbear to mention that Landau was actually correct all along; the critical velocity for the onset of non-vortex dissipation, subsequently measured at Lancaster, was in excellent quantitative agreement with the original Landau prediction.

The saga is likely to be of interest to historians and philosophers of science. It will certainly provide fascinating reading for physicists, and in particular for all those involved in research at low temperatures. □

## Metastatic Spread of Cancer

G.V. Sherbet

This book outlines a new approach to the analysis of the mechanisms of metastasis by comparing the glioma, an intracranial tumour which ordinarily does not metastasize, to other metastasizing tumour models. This has produced a coherent picture of the operation of oncogenes and growth factors in the initiation, development and progression of neoplasms. This is an essential book for those researching metastasis and will be of interest to all research oncologists.

## Greater clarity on crystals

Alan L. Mackay

**Introduction to Quasicrystals.** Edited by Marko V. Jarić. *Academic:1988. Pp.285. £31.50, \$50.*

MOST textbooks on crystallography and solid-state physics begin with the (still undoubted) proposition that, in an infinite crystallographic lattice, lattice points, all of which have identical surroundings, cannot have fivefold symmetry. Their authors also assume, and would like to prove, that the most stable state of an assembly of identical units is a crystal. They fail to prove this proposition rigorously, perhaps because it may not be true, and then continue with the physics of crystals.

Crystallographers have long been aware of the existence in crystals of molecules and clusters of icosahedral symmetry, and of the frequent incompatibility of the local symmetry of such groups with the limited point-site symmetries available in the 230 crystallographic space groups. Fivefold or icosahedral symmetry in extended crystals was universally assumed to be impossible. It was, therefore, a tremendous surprise when, in 1984, Dan Shechtman and his colleagues at the National Bureau of Standards in the United States reported that extended regions of a rapidly quenched alloy, of composition about Al<sub>63</sub>Mn, showed electron-diffraction patterns with sharp spots and with full icosahedral symmetry. Since the appearance of their paper, some 600 further papers on the new structures, now called 'quasi-crystals', have been published. With the present volume we now have the first book on the topic, presenting the material in more digestible form (a convenient basic compendium of papers, with commentary, had earlier been produced by Steinhardt and Ostlund).

There is nothing actually wrong with the crystallographic rules which we knew before 1984, but we have had to look much more closely at the gaps between them. Curiously, the phenomenon turns on unobserved phase angles. In X-ray diffraction from crystals, the Bragg's insight was to see that each spot in the diffraction pattern corresponded to a sinusoidal density wave of scattering matter and that the crystal could be considered as the linear superposition of these. The amplitudes of the waves are easily recorded but their phases are not. It is the art of X-ray crystal structure analysis to recover them.

The 230 space groups prescribe the symmetry relationships between the phases from the assumption of crystallicity. We are still free to make structures

with some particular symmetry for the amplitudes but no necessary symmetry for their phases, which may also vary from place to place in the material. People had assumed that any structure that gave diffraction patterns with sharp spots must be periodic. It has now been shown that materials with two incommensurate periodicities combined in the right way (by being a section through a higher-dimensional lattice), or being quasi-periodic in the strictly mathematical sense of the term, also show sharp spots.

It turns out that quasi-crystals exploit this unobservability of the phases. The diffraction effects may have icosahedral symmetry but that does not mean that there are fivefold axes in the structure. Since about 1974, the Penrose tiling has been known as a mathematical game and it was immediately seized upon as a patterning system which would produce diffraction phenomena like those observed. The Penrose tiling exemplified the extremely ingenious compromise found by nature between the demands of local icosahedral order and of long-range order.

Since 1984 the matter has become immensely more complicated. In the 1930s crystallographers discussed all kinds of structures between perfect crystals and glasses, and indeed the possibility of icosahedral textures was explicitly mentioned. But recently the initiative has passed to the solid-state physicists, who have attacked the area in massive strength.

In this volume, the first of a series entitled "Aperiodicity and Order", Marko Jarić has collected together six essays which lay out the new subject coherently. To start with, David and Clara Shoemaker describe the local icosahedral coordination often observed in metallic crystals, some of great complexity, which lays the foundation of local order — one of the consolations of ageing is that one can enjoy seeing their stereo-pairs without a stereoscope. Michael Widom looks at short- and long-range order more generally, introducing the intriguing relevance of four-dimensional polytopes as poly-tetrahedral structures with local icosahedral coordination, and discussing how they may be decurved back into the normal three-dimensional world in which the quasi-crystals must exist. Robert Schaefer and Leo Bendersky then provide a metallurgical setting for the occurrence of quasi-crystalline phases.

Per Bak and Alan Goldman begin on the new quasicrystallography, showing how structures with the necessary diffraction properties can be derived as projections of lattice structures in higher dimensional space. The phases with icosahedral diffraction symmetry can be derived as three-dimensional sections through a six-dimensional hypercubic lattice. Accordingly, diffraction spots can be assigned six-

integer indices with respect to this lattice; there is an analogy with the way in which ordinary hexagonal crystals are given four indices with respect to a four-dimensional lattice.

The remaining two chapters — "Stability and Deformation" by O. Biham, D. Mukamel and S. Shtrikman, and "Symmetry, Elasticity and Hydrodynamics in Quasiperiodic Structures" by T.C. Lubensky — take the reader into the field of solid-state physics rather than conventional crystallography. It is clear that crystallographers will have to absorb this new material. It might even be said that while they have been away capturing large areas of biology, the physicists have moved in and occupied the central camp of crystallographic theory. Crystallographers have become the victims of their own success (based on crystal structure analysis); phases, such as liquid crystals, which were somewhat disdained as being

inferior, have been taken over by solid-state physicists who have applied sophisticated theoretical analyses which crystallographers can hardly match.

Altogether, the quasicrystal episode has been of the greatest interest. The whole area of crystal symmetry — which is often quoted as being one of the most tightly sewn up with a beautiful and complete theory — has been broken open by an experimental observation, resulting in a mass of exciting new theories, many of which can be connected with actual materials. We can look forward to further books on the subject, where the new ideas will be laid out with increasing clarity and simplicity. The opening chapters of all volumes on crystallography and solid-state physics must henceforth begin differently. □

Alan L. Mackay is a Professor in the Department of Crystallography, Birkbeck College, Malet Street, London WC1E 7HX, UK.

print: "The work of the last ten years has emphasized the extreme difficulty of producing any really quantitative theory".

The appearance of Alan Cottrell's new book *Introduction to the Modern Theory of Metals* is indicative that the theoretical physicists have now put their house in order and can offer the metallurgist reliable quantitative insights into the world of metals at the atomic level. The magic touch, which he displayed in his earlier textbooks on metallurgy, is still very much in evidence as he describes the developments of the past 30 years that have placed the modern theory of metals on such a firm foundation. Coming from outside the field of electron theory himself, he offers a broad vision and a clarity of purpose.

The book begins with a discussion of the fundamental question 'What is a metal?'. The recent discovery of high-temperature superconductivity in ceramic oxides has driven home the fact to a wide audience that Wilson's original distinction between metals and insulators in terms of energy bands and Brillouin zones is fatally flawed. Cottrell stresses that physicists and chemists are now converging in their views on highly correlated systems — Mott's famous criterion for the metal-insulator transition being similar to a pre-quantum treatment of the problem as a polarization catastrophe by Herzfeld and Goldhammer, and Anderson's model of high-temperature superconductivity building on Pauling's ideas of the resonating valence bond. One-electron energy-band theory is, however, shown to be well justified for normal metals in which the electrons are less highly correlated. Excellent chapters introduce the ideas of quasiparticles, pseudopotentials and density functional theory which are at the heart of modern quantitative electron theory. Others discuss the cohesion and structure of simple metals, transition metals and their surfaces, and recent theories of alloy formation.

*Introduction to the Modern Theory of Metals* will be essential reading for students of metallurgy and solid-state physics. The mathematics is kept to a minimum within the main text, the more detailed working and theory being relegated to appendices, so that in Cottrell's hands even the mathematically weakest student should be able to follow the physical arguments. Research workers wishing to understand recent advances in the electron theory of metals will also find the book invaluable. With industrial laboratories the world over engaging electron theorists to help them in the search for new and better alloys, Raynor's optimism no longer appears to be so misplaced. The electron theory of metals has come of age. □

D. G. Pettifor is a Professor in the Department of Mathematics, Imperial College, Prince Consort Road, London SW7 2AZ, UK.

## Electronified

D. G. Pettifor

**Introduction to the Modern Theory of Metals.** By Alan Cottrell. *Institute of Metals, 1 Carlton House Terrace, London SW1Y 5DB/Old Post Road, Brookfield, Vermont 05036:1989. Pp.260. £35, \$73.50.\**

THE classic textbooks by Hume-Rothery and Raynor on the electron theory of metals were published soon after the end of the Second World War. They were imbued with the optimism, prevalent at that time amongst scientists, that science could win the peace just as it had helped win the war. In response to the query why metallurgists should know about quantum theory, Raynor writes in his 1947 preface: "If the metallurgists of [Britain] do not learn about electron theories, they may discover, too late, that industry in other countries has benefited from knowledge of modern theories and is developing new alloys".

This belief in the power of electron theory to place the metallurgical industry on sound scientific foundations did not seem misplaced. Hume-Rothery's pioneering work on the solubility limits and crystal structure of copper, silver and gold alloys had been given a simple theoretical

explanation by Jones in 1934. Experimentally, the maximum solubility of polyvalent elements such as zinc, aluminium or tin in the monovalent noble metals was found to occur at an average number of valence electrons per atom of approximately 1.4 (assuming a valence of 1, 2, 3 and 4 for copper, zinc, aluminium and tin respectively). Jones pointed out that this was very close to the number of electrons per atom which is required for the spherical free-electron Fermi surface to make contact with the Brillouin zone boundary corresponding to the face-centred cubic lattice of the noble metals. Further solute atoms would push electrons into the high-energy states across the gap at the zone boundary. This is energetically unfavourable and Jones predicted the face-centred cubic lattice would undergo a transformation to the body-centred cubic lattice, as is observed experimentally.

Alas, this optimism in the usefulness of modern theory for alloy development was dashed ten years later when, in 1957, Pippard discovered that the Fermi surface had already made contact with the Brillouin zone boundary in elemental copper, even though the electron per atom ratio was only one. The approximation of treating copper's valence electrons as a gas of free electrons which are only weakly perturbed by the ionic lattice — a problem which theorists could solve — was simply too crude. In practice, the full 3d electronic shell in copper is not inert but hybridizes strongly with the valence sp band, thereby giving copper its characteristic colour and high cohesive energy. At the time, however, controversy surrounded how best to treat the valence d electrons in transition and noble metals — whether to regard them as localized on their parent atoms or itinerant. As Hume-Rothery wrote in the preface to the 1962 fourth (revised) re-

\* To coincide with the publication of Cottrell's book, The Institute of Metals has reprinted three titles on the same or related topics — *Atomic Theory for Students of Metallurgy*. By W. Smallman, W. Hume-Rothery and C. W. Haworth. Pp.407. Pbk £18, \$37.80.

## Mother love

Leonard Krishtalka

**Digging Dinosaurs.** By John R. Horner and James Gorman. Workman Publishing, New York: 1988. Pp.210. \$17.95.

A HUNDRED years ago in the American West, a 'bone pilgrim' was a cowboy who collected dead animal bones and sent them east for processing into artificial manure. Roaming the West at the same time was a second, lesser known, breed of bone pilgrim, one who collected fossil animal bones and sent them east for processing into scientific manuscripts. Jacob Wortman, Charles Sternberg, William Reed, John Bell Hatcher and others were bone pilgrims of this sort for Pittsburgh's Carnegie Museum, New York's American Museum of Natural History, Yale's Peabody Museum and Princeton University. Today they would be called 'field palaeontologists'.

John Horner, curator of palaeontology at the Museum of the Rockies in Bozeman, Montana, would have made a fine bone pilgrim in the Old West because he is one of the finest field palaeontologists in the New West. In August 1978 Horner, then a preparator of fossils at Princeton, and his friend Bob Makela, a high-school science teacher in Montana, followed the owners of a local rock shop up a windswept knob of red and green mudstone on the plains near Choteau, Montana. Back at the rock shop lay bits of a thigh bone, a rib and a jaw of a baby hadrosaur (a duck-billed dinosaur) that the owners had found on the surface.

Horner and Makela combed the knob, and in the scree found the remains of two more baby hadrosaurs. The bones were concentrated in a bowl-shaped mass of green mudstone, a nest scooped out by the hadrosaur mother 80 million years ago. The dinosaur was a new genus, later named *Maiasaura*, 'good mother lizard'. Horner and his colleagues spent the next six years in Montana exhuming the ancient life of *Maiasaura* from the knob and surrounding rock — 14 nests, 42 eggs, three nesting grounds, 31 babies and a gigantic herd of 10,000 individuals. The excavations also uncovered the extraordinary record — 25 skeletons, 14 clutches of eggs and 19 eggs with embryonic skeletons — of a second dinosaur, a new genus of hypsilophodontid.

In a field beset by hyperbole, it is fair to say that Horner's discoveries are unparalleled. Two square miles of late Cretaceous rocks reveal geological moments when female maiasaurs and hypsilophodontids gathered in birdlike flocks on communal nesting grounds and laid their eggs. On hatching, the young maiasaurs (which were apparently altricial) stayed in their

## AWFUL CHANGES

MAN FOUND ONLY IN A FOSSIL STATE — REAPPEARANCE OF ICHTHYOSAURI.

A Lecture — "You will at once perceive," continued Professor Ichthyosaurus, "that the skull before us belonged to some of the lower order of animals; the teeth are very insignificant, the power of the jaws trifling, and altogether it seems wonderful how the creatures could have procured food."

The cartoon, from Francis T. Buckland's *Curiosities of Natural History* (1859), is reproduced in *Dinosaur Plots and Other Intrigues in Natural History* by Leonard Krishtalka, published by William Morrow, which will be reviewed in *Nature's Spring Books* issue next week.

nests and were fed and cared for by their good mother lizard; the hypsilophodontid hatchlings, comparatively more mature, left the nests immediately after birth. Both species, like birds, grew quickly and were warmblooded. The maiasaurs, like modern wildebeest, travelled in herds several thousand strong.

*Digging Dinosaurs*, which is co-written with James Gorman, is Horner's personal account of this revolutionary dinosaur diorama and the good fortune, perseverance and palaeontological detective work behind its discovery and reconstruction. Horner is folksy. He toasts the co-evolutionary ties of bonehunters and beer, using the tab of a Rainier beer can for scale in an illustration of baby maiasaur bones. Not much has changed in a hundred years of bonehunting: the field pictures are no longer black and white, the field crews no longer wear black suits and bow-ties in the quarry, and mule teams no longer haul out the dinosaur blocks. But that is about all. What has changed is the picture we have of the dinosaurs themselves, no longer cloddish and dimwitted, but hot, nimble, social and caring.

The book captures the romance, realism and scientific implications of Horner's field work and astonishing discoveries. The friendly, unassuming tone is tailored

for a general audience; those hungry for the straight, academic treatment of the evidence can refer to his papers in the scientific journals. Once in a while Horner's folksy science is, as they say in the West, bodaciously wrong — life evolved at least 3.5 not 2 billion years ago (pp. 38–39), and Darwin never called natural selection 'survival of the fittest' (p.66), Herbert Spencer did. Some critics have already demanded more evidence for maternal care among maiasaurs. Others question Horner's proposition that volcanic gassing and catastrophic flooding turned a herd of 10,000 of them into a graveyard of dismembered, shattered skeletons.

But these are the rough and tumble issues in *Digging Dinosaurs*. When it comes to dinosaurs, the palaeontologist's mind until recently was a prisoner of conventional attitudes that kept the beasts stiff and cold. As Horner says, "palaeontology can grow sleepy and accumulate dust like museum cellars" were it not for challenges to the prevailing wisdom. Those challenges have wrought a dinosaur renaissance during the past two decades, a new manifesto for the Mesozoic. □

## **The Complement System**

1988. 70 figures. XV, 535 pages. Hard cover DM 180,-.  
ISBN 3-540-18205-5

The serum complement system plays an essential part in understanding inflammation processes and body defense mechanisms. This excellent book offers the only broad coverage of the field and integrates in separate chapters the physicochemical and biological aspects of the complement system. Special attention is paid to the biology of split products generated along the different activation pathways and to the cooperation of the biologically active split products in the pathogenesis of pathological conditions such as inflammatory reactions, graft rejection, allergic shock, side reactions to drugs and host defense against infections.

1988. 63 figures,  
47 tables.  
XXII, 247 pages.  
Hard cover DM 165,-.  
ISBN 3-540-50247-5

This is the first book devoted completely to Complex Formation by Histocompatibility Antigens (MHC+X). It concentrates firstly on the question of whether neodeterminants resulting from the interaction of MHC with foreign antigen can also be recognized by antibodies. Thus the question of MHC restricted antibodies is discussed in detail. Secondly, the book provides information on how the complex (MHC+X) is recognized by T cells. Finally, information about recent findings on other, nonimmunological functions of the MHC is given. The contributions stem from a broad panel of researchers from various countries; their views show the very different aspects of MHC function.

### **Molecular Mimicry**

#### **Cross-Reactivity Between Microbes and Host Proteins as a Cause of Autoimmunity**

1989. 28 figures, 16 tables. Approx. 165 pages. Hard cover DM 108,-. ISBN 3-540-50929-1

In this volume, contributions from recognized experts present their original findings, focusing on the evidence for or against molecular mimicry as a cause of autoimmunity. The final chapter reviews the overall perspective of molecular mimicry, and how to use its principles in clinical investigation, and lists the conceptual traits by which autoimmune disease can occur.

Volume 146  
J. Mestecky, J. R. McGhee, University of Alabama (Eds.)

### **New Strategies for Oral Immunization**

International Symposium at the University of Alabama at Birmingham and Molecular Engineering Associates, Inc. Birmingham, AL, USA, March 21-22, 1988

1989. 22 figures. X, 238 pages. Hard cover DM 124,-.  
ISBN 3-540-50841-4

Various vaccines that lead to the induction of antibodies in respiratory, gastrointestinal, and genitourinary tracts are currently under development, and others are in use for the immunization of animals as well as humans. This volume gives oral immunization the attention it deserves in light of recent methodological and technical advances in antigen delivery systems.

# Advances in Electrophoresis

This long-awaited new serial aims to provide critical reviews of selected techniques or important areas of application of electrophoresis. Rather than summarizing all available information, the reviews present the essence of each topic and demonstrate its potential. The reviews appeal to the great many readers who use electrophoretic techniques but do not follow systematically their development in the original literature. This publication is indispensable to those interested in the application of new techniques or entering a field requiring the use of electrophoresis.

# Climate change in the circum-North Atlantic region during the last deglaciation

Jonathan T. Overpeck\*, Larry C. Peterson†, Nilva Kipp‡, John Imbrie‡ & David Rind§

\* Lamont-Doherty Geological Observatory of Columbia University, Palisades, New York 10964, USA

† Rosenstiel School of Marine and Atmospheric Science, University of Miami, 4600 Rickenbacker Causeway, Miami, Florida 33149, USA

‡ Department of Geological Sciences, Brown University, Providence, Rhode Island 02912, USA

§ NASA Goddard Institute for Space Studies, 2880 Broadway, New York 10025, USA

A survey of new and published palaeoclimate data indicates that both the high- and low-latitude North Atlantic regions were characterized by at least three synchronous periods of abrupt climate change during the last glacial-to-interglacial transition. Climate model results suggest that changes in the melting history of the Laurentide Ice Sheet may explain much of this nonlinear response of the climate system to astronomical (Milankovitch) forcing.

ASTRONOMICAL or Milankovitch forcing has become established as the primary 'pacemaker' of the ice ages, accounting for much of the total observed climatic variance of the late Quaternary<sup>1,2</sup>. Most climatic variance at frequencies lower than 1 cycle per 19,000 years is related to astronomical forcing, and even abrupt glacial terminations can be partially attributed to such forcing<sup>3</sup>. A closer look at the last glacial-interglacial transition, however, reveals a sequence of climate change that cannot be explained as a simple linear response to astronomical forcing. Marine and terrestrial records of environmental change in the high-latitude North Atlantic, Greenland and Europe reveal a period of rapid climatic warming at ~13–12.6 kyr BP, followed by an abrupt reversal towards colder glacial conditions at ~11 kyr, and a second rapid warming to interglacial conditions at ~10 kyr (refs 4–7). The abrupt 13-kyr warming and the 'Younger Dryas' cold event between 11 and 10 kyr were apparently more pronounced over Greenland and Europe than over North America, an observation that has led workers to surmise that changes in the heat budget of the high-latitude North-Atlantic produced the changes over land<sup>5–9</sup>. Ruddiman<sup>4</sup> proposed that a reduction in ice-sheet height over North America could have rapidly reduced the amount of cold air advected

over the North Atlantic, thus allowing the North Atlantic and downstream Europe to warm abruptly at ~13 kyr. Ruddiman<sup>4</sup> and Broecker *et al.*<sup>5</sup> expanded on earlier work<sup>10–13</sup> to suggest that major diversions of Laurentide Ice Sheet meltwater between the Mississippi and St Lawrence rivers may have caused the North Atlantic, Greenland and Europe to cool at the beginning of the Younger Dryas period (~11 kyr) and then warm abruptly at the end of the Younger Dryas period (~10 kyr). General Circulation Model (GCM) results support the dominant role of North Atlantic sea surface temperature (SST) fluctuations in forcing high-latitude climate change<sup>6,9</sup>.

Here we try to place the observed high-latitude pattern of climate change into a more global perspective. First, we examine new and published data from the Caribbean and Gulf of Mexico region that also point to systematic patterns of abrupt change at ~13–12.6, 11 and 10 kyr. We then examine new and published climate model results which suggest that much of the low-latitude pattern of change can be linked to variations in meltwater discharge down the Mississippi and St Lawrence rivers, and the sea surface temperatures of the high-latitude North Atlantic and Gulf of Mexico. Our results lead us to speculate that rapid climate events over Africa may also have been related to these same variations. We conclude with the hypothesis that the climate system translated the relatively gradual astronomical forcing, characteristic of the past 18 kyr, into an inter-related sequence of abrupt climate events over an extensive area of the globe.

## Caribbean and Gulf of Mexico regions

In this section, we look at the patterns and sequence of climate change which occurred around the Caribbean and Gulf of Mexico during the last deglaciation. In particular, we focus our initial attention on data derived from an investigation of sediments from the Cariaco Basin (10°40' N, 65° W), a small (160 × 40 km), deep (1,400 m) anoxic marine basin aligned along the northern continental margin of Venezuela. This margin is

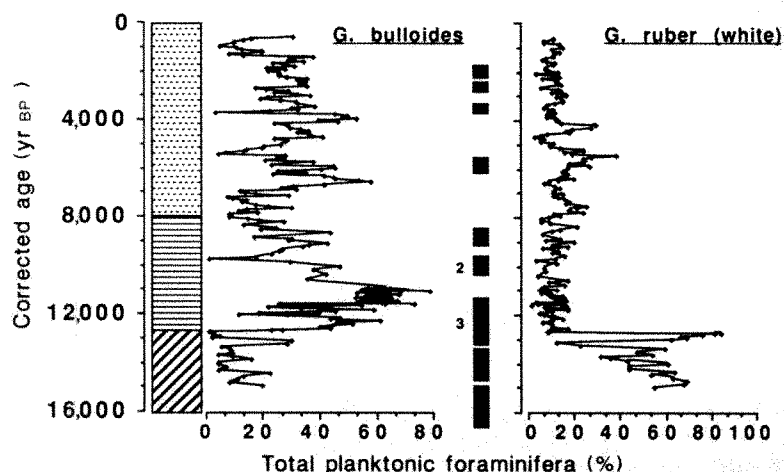

FIG. 1 Time series of *G. bulloides* and *G. ruber* relative abundance for core V12-99 from the Cariaco Basin. Also shown are core lithology and the distribution of radiocarbon-dated intervals which were biostratigraphically correlated from the closely matching, but less continuous, core V12-104. This series of dates did not include any reversals. All dates were adjusted by 400 years to correct for the difference between surface water and atmosphere radiocarbon content. The V12-104 record is less continuous due to the presence of turbidites that were not present in V12-99. ■, radiocarbon-dated intervals (2, 3 = number of dates); Sediment type: □, weakly laminated calcareous clays; ■, strongly laminated calcareous clays; ▨, weakly bioturbated calcareous clays.

currently characterized by Ekman-induced coastal upwelling, with cold SSTs found during the dry winter/spring season of greatest along-shore wind stress, and warmer SSTs during the less windy wet summer season<sup>14,15</sup>. Plankton tow data from the Cariaco Basin indicate that seasonally high abundances of phytoplankton (mainly diatoms) and the planktonic foraminifer *Globigerina bulloides* dominate the water-column assemblage during the upwelling season, whereas *Globigerinoides ruber* is abundant during the non-upwelling season<sup>16</sup>.

The strong seasonality in the wind-induced coastal upwelling is reflected in the faunal and lithological character of the laminated sediments which accumulate rapidly (20–100 cm kyr<sup>-1</sup>) beneath anoxic waters in many portions of the Cariaco Basin. Piston cores V12-99 (1,005 m water depth) and V12-104 (466 m) were sampled on average every 3 and 1 cm, respectively, for a complete foraminiferal census. Age control is provided by twelve radiocarbon dates on bulk carbonate (Fig. 1). We subtracted 400 years from each date to account for the difference in radiocarbon content between the surface waters and atmosphere<sup>7</sup>. The two piston cores, separated by over 50 km, yielded nearly identical time series of foraminiferal abundance, indicating that our faunal records are probably representative of the basin as a whole. We focus here on the abundance record of *G. bulloides* in V12-99 as a proxy record of upwelling, and hence trade-wind intensity (Fig. 1). We will elaborate further on the very detailed Cariaco Basin record elsewhere. Like the high-latitude records of climatic change, the Cariaco Basin record shows evidence of rapid change at ~13–12.6, 11 and 10 kyr.

The presence of weakly bioturbated sediments, the high abundance of *G. ruber*, and the low abundance of *G. bulloides*

near the base of the core (Fig. 1) suggest that lowered sea level may have isolated the Cariaco Basin sufficiently to prevent active Ekman-pumping during the last glacial maximum. At 12.6 kyr, both cores record a significant increase in sedimentation rate, an abrupt change from bioturbated to distinctly laminated anoxic sediments (traceable over the entire basin), and a sudden shift in foraminiferal assemblages from a non-upwelling fauna to samples dominated by *G. bulloides*. High concentrations of *G. bulloides* during the period 12.6–10.8 kyr (>2,000 individuals g<sup>-1</sup> compared to a core mean of <500) suggest that the high sedimentation rates observed throughout this period (>80 cm kyr<sup>-1</sup> compared to the core mean of <40) were related to intense upwelling and high productivity of *G. bulloides*. The abundance of *G. bulloides* drops abruptly after 10.8 kyr, but remains at levels above the Holocene mean. This change suggests that upwelling and trade-wind intensities, although diminished, were still high during the period 10.8–10 kyr. A further decline in the abundance of *G. bulloides* after 10 kyr suggests that the Holocene mode of moderate (although still highly variable) upwelling began at this time.

The Cariaco Basin upwelling record provides evidence for rather abrupt changes in trade-wind strength at ~12.6, 10.8 and 10 kyr, with the strongest trade winds over the southern Caribbean found between 12.6 and 10.8 kyr. Independent palaeoclimate data from the region support the abrupt nature of change at these times. In the lowlands adjacent to the Caribbean, pollen and lake-level records indicate that glacial (18 kyr) aridity persisted until shortly after 11 kyr, when moist conditions suddenly prevailed<sup>17–19</sup>. To the north of the Gulf of Mexico and Caribbean region, the deglacial sequence of climate change is less clear.

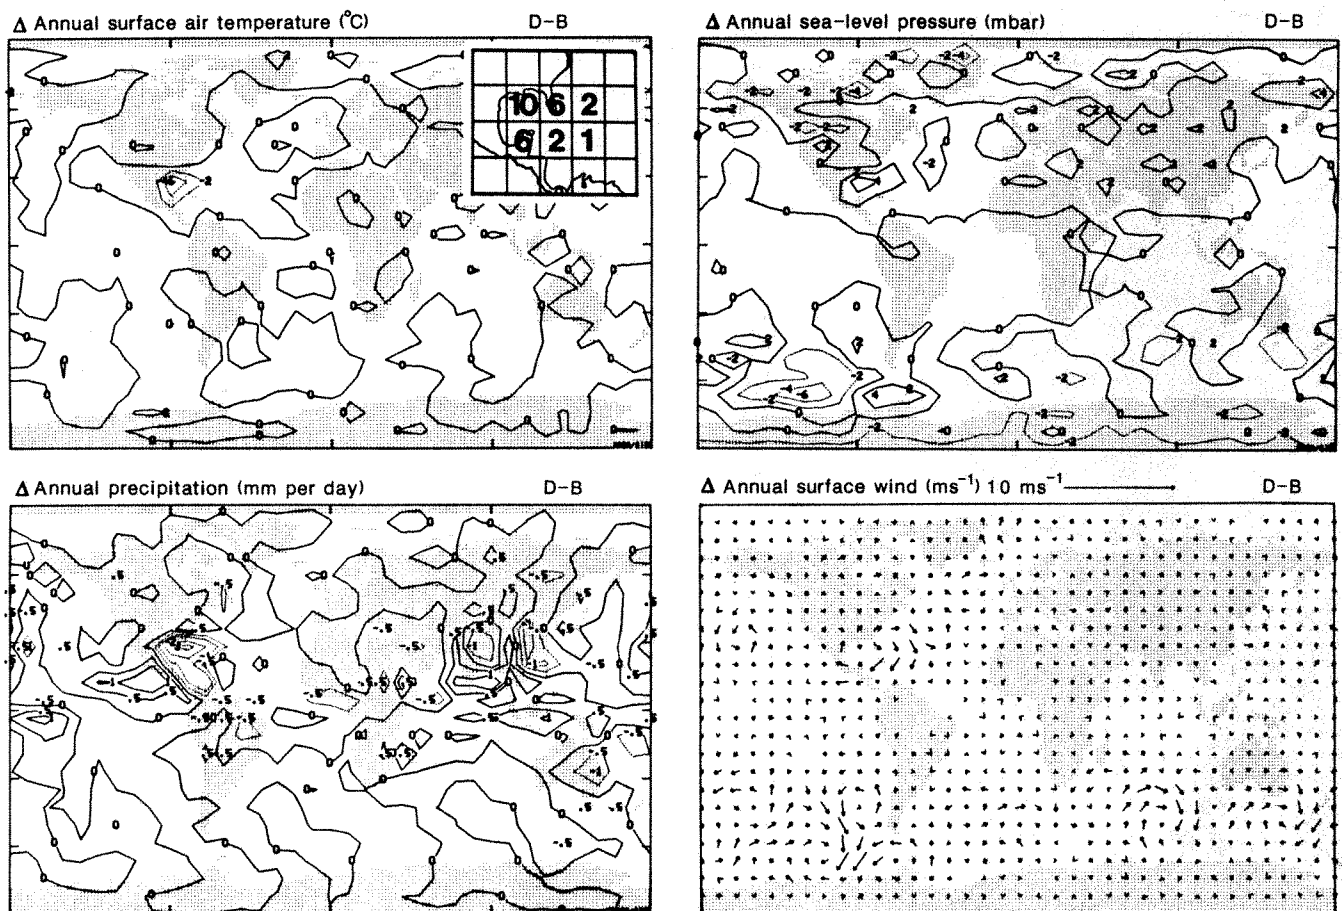

FIG. 2 Simulated mean-annual differences between experiment D and B. Inset shows the magnitude of the negative (°C) SST anomalies (relative to

the present-day) that were prescribed for six model grid points in experiment D (see Table 1 and text for more details).

Water levels in low-elevation lakes throughout the southeast US Coastal Plain were low or lakes were dry from before 18 kyr until after 15 kyr, when lake levels rose in response either to increased precipitation, rising sea level, or both<sup>20</sup>. A similarly equivocal record of past hydrological change in this region is the poorly dated record of fluvial changes which seems to indicate moist conditions until 13 kyr (refs 21, 22). Pollen records from the southern Coastal Plain<sup>20,23–27</sup> show abrupt change at 13 and 11 kyr. Increased amounts of herb pollen and decreased abundances of *Carya* pollen may argue for aridity between 13 and 11 kyr in Florida<sup>20,23,24</sup>, just as increased amounts of *Fagus* and *Liquidambar* pollen may have signalled the onset of wetter conditions after 11 kyr further north<sup>25–27</sup>. More data are clearly required, however, to refine this regional picture.

### Observed versus simulated palaeoclimatic change

The apparent synchronicity between events in the Cariaco Basin record, in other records from the Caribbean and Gulf of Mexico region, and in records from the high-latitude North Atlantic suggest a common forcing mechanism during deglaciation. In particular, the evidence for stronger trade winds between 12.6 and 10.8 kyr in the western North Atlantic and for Gulf/Caribbean aridity until ~11 kyr have led us to examine the effects that a cool Gulf of Mexico may have had on the climate system. Geological data from North America and stable isotope data from Gulf sediments suggest that the flow of cold, fresh Laurentide Ice Sheet meltwater down the Mississippi River and into the Gulf of Mexico began at ~15–14 kyr, waned slightly from ~14–13 kyr, and peaked between 13 and 11 kyr before being diverted down the St Lawrence River into the high-latitude North Atlantic<sup>5,9–12</sup>. During the interval of maximum discharge into the Gulf, which coincides closely with the timing of events described above, the volume of Mississippi outflow must have been immense (5–11 times the present annual discharge, but mostly confined to the spring–summer meltwater season<sup>13,28</sup>), apparently included seasonal ice-rafted detritus (R. Saucier, personal communication), and was sufficient to affect sea surface salinities well out into the western North Atlantic<sup>13,29</sup>. Unlike the role of salinity, little attention has been paid to the possible consequences of meltwater-induced temperature change in the Gulf of Mexico. Independent data<sup>30,31</sup> suggest that the open south-west Caribbean did not warm from glacial values until ~11 kyr, and it seems likely that the more northerly Caribbean and Gulf of Mexico regions may have been cooled even further by the large influx of glacial meltwater. We suggest that cooler Gulf SSTs during peak meltwater discharge could provide a mechanism for explaining observed events if the cooling was sufficient to produce a high regional surface-pressure anomaly, which would in turn strengthen western Atlantic trade winds and suppress precipitation.

To test this hypothesis, we compared the results from four GCM ( $8^\circ \times 10^\circ$  latitude by longitude grid size) experiments (for details, see Table 1) using the Goddard Institute for Space Studies model<sup>6,32</sup>. Experiment A represents our model simulation of the current (warm) climate. The results of the four-year experiments, B and C, were compared to test the sensitivity of the global climate system to the hypothesized Younger Dryas (~11–10 kyr) reduction in North Atlantic SSTs<sup>6</sup>. We also ran a two-year experiment (D) to test the sensitivity of the climate system to cooled Gulf of Mexico SSTs during the period ~13–11 kyr. Experiment D was identical to B, except that model grid points which included the Gulf of Mexico and adjacent water were cooled by ~6 °C on average (Fig. 2). Unfortunately, the palaeoceanographic record provides no direct evidence for cooling of the Gulf by meltwater. However, the oxygen isotope record of meltwater<sup>10,11,13,29</sup> is useless in this regard because of the predominance of salinity effects, and existing microfossil-based studies of Gulf SSTs<sup>33,34</sup> have sample spacings that may preclude recognition of such a brief (2-kyr) event. In the absence of data to the contrary, we selected an average cooling of 6 °C

based on estimates of meltwater volume, on the observation that present-day Mississippi River water is up to 10 °C colder than Gulf surface waters<sup>28,35</sup>, and on the observation that downstream Caribbean SSTs were probably already depressed by 2–3 °C before they warmed at 11 kyr to Holocene levels<sup>30,31</sup>. Independently, Oglesby *et al.*<sup>28</sup> have arrived at a similar estimate and, more importantly, have performed sensitivity tests which suggest that an even smaller cooling could still have forced the same patterns of change around the Gulf that we have forced with our SST anomaly.

Our simulated cooling of the Gulf of Mexico (D minus B) produced lower surface air temperatures, higher sea-level pressure, a large negative precipitation anomaly, and a more vigorous anticyclonic surface air circulation over the Gulf of Mexico and Caribbean region (Fig. 2). Each of these changes is statistically significant (greater than several standard deviations of the inter-annual changes found in experiment B) and agrees with the palaeoclimatic data described in the previous section. The simulated difference between experiments D and A indicate that a cool Gulf of Mexico between ~13 and 11 kyr is needed to match the palaeoclimatic evidence for greater than present aridity around the Gulf and Caribbean region, and more intense trade winds in the western North Atlantic. Averaged over the annual cycle, the cooling of the Gulf produced no significant temperature anomalies outside the Gulf/Caribbean region. In our experiment, the well-developed higher pressure and cooler temperatures in the Gulf region helped divert storm tracks northward, resulting in both lower pressure and a small band of increased precipitation north of the Gulf Coastal Plain. This pattern agrees with the observation that aridity may have been restricted to Florida and Georgia between ~13 to 11 kyr. Slightly higher precipitation values, probably indicative of increased Hadley circulation, were also simulated equatorward of the Gulf of Mexico over the northern Amazon Basin and central Andes. These changes were not as significant (less than three standard deviations) as those simulated around the Gulf of Mexico and Caribbean region, but they do appear to agree with the sparse palaeoclimate data from South America<sup>36,37</sup>.

Rind *et al.*<sup>6</sup> compared C and B to demonstrate the importance of high-latitude North Atlantic SSTs in forcing the observed climate changes over North America, Greenland and Europe during the last glacial–interglacial transition. Our comparisons of D with B (Fig. 2) and C with D (Fig. 3) support this conclusion. On a yearly average basis, the observed high-latitude variations in both precipitation and temperature appear to be explained by the observed changes in high-latitude SSTs: rapid warming at ~13 kyr, rapid cooling at ~11 kyr (the onset of the Younger Dryas) and rapid warming again at ~10 kyr (the end of the Younger Dryas). At lower latitudes, the warming of the Gulf at ~11 kyr can explain the wetter conditions and slight wind relaxation observed at this time in the western North Atlantic/Gulf/Caribbean region (Fig. 3). The magnitude of the

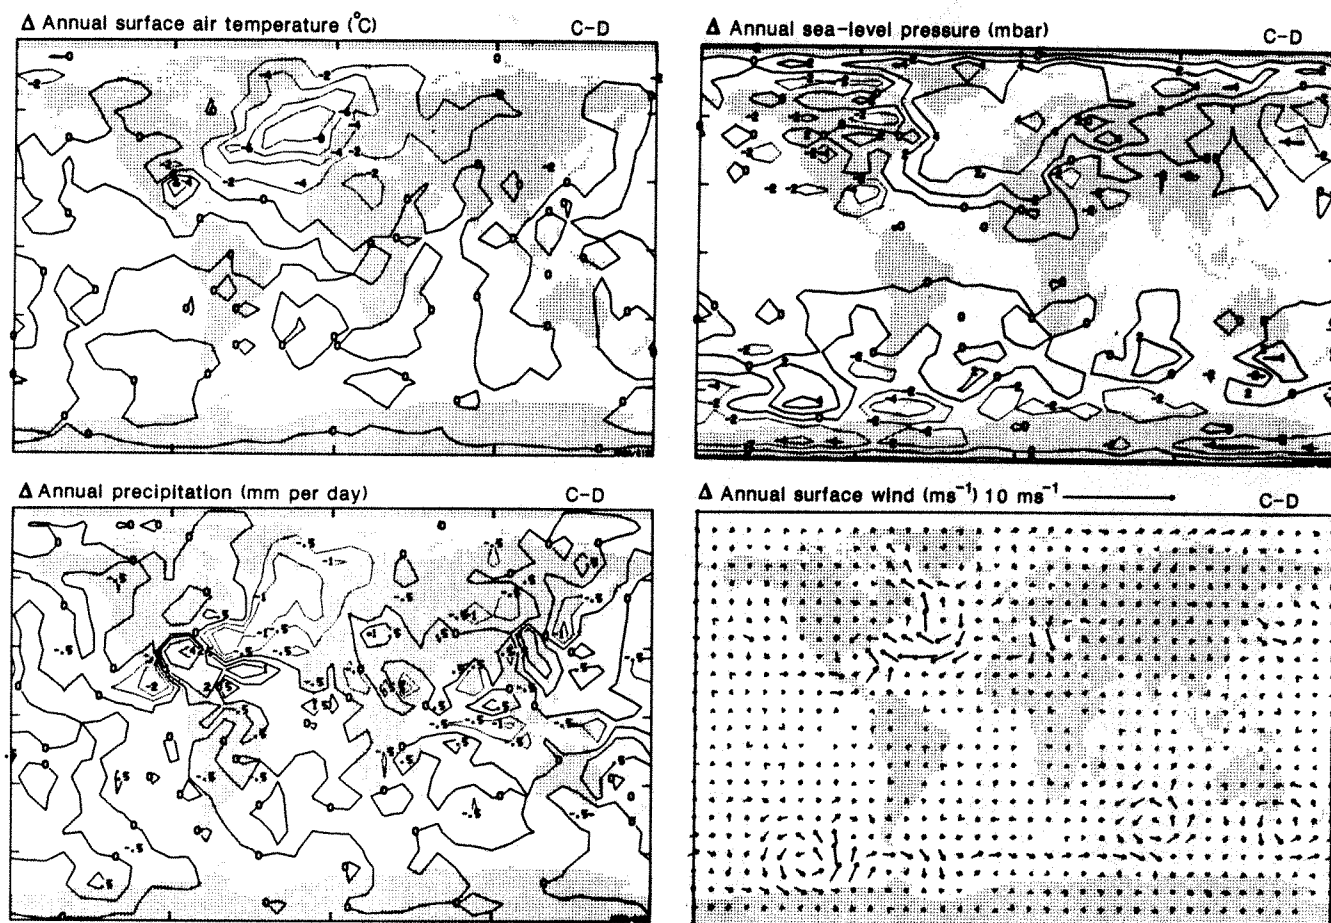

FIG. 3 Simulated mean-annual differences between experiment C and D (see Table 1 and text for more details).

Gulf/Caribbean aridity probably would have been enhanced between 13 and 11 kyr had we prescribed colder SSTs along the northern South American margin in accordance with the Cariaco Basin upwelling record.

Our simulations suggest that the observed pattern of climate change over most of the circum-North Atlantic region can be explained by the proposed effects of cold Laurentide Ice Sheet meltwater on SSTs of the high-latitude North Atlantic and Gulf of Mexico. Our model results may not, however, provide a complete physical explanation for the sequence of change observed over North Africa, and, in particular, for the arid event that apparently was synchronous with the Younger Dryas in Europe ( $\sim 11$ –10 kyr, refs 38–46). The increased surface pressure and stronger easterly surface winds in experiment C relative to D (Fig. 3) support the idea<sup>39,44</sup> that a colder North Atlantic could have stabilized the lower atmosphere and helped block the advection of moisture over North Africa. However, the simulated precipitation changes between the two experiments are somewhat ambiguous (Fig. 3). Additional experiments are needed to examine the significance of the precipitation anomalies in East and North Africa. It is also necessary to test the possibility that abrupt changes of high-latitude North Atlantic SSTs were associated with other rapid changes that could have contributed to the observed changes over North Africa. Higher atmospheric aerosols<sup>47</sup>, changes in vegetation, a weaker monsoon, and lower-latitude Atlantic SST cooling<sup>48</sup> may all have helped to make North Africa more arid before  $\sim 13$ –12.6 kyr, and between 11 and 10 kyr.

### Conclusion

Our postulated synchronicity of rapid climate events at  $\sim 13$ –12.6, 11 and 10 kyr around the circum-North Atlantic must be tested

by means of the acquisition of additional well-dated, high-resolution palaeoclimate records. In most cases, we were forced to use dates with an uncertainty of  $\sim 5$ –10% to infer synchronicity. In addition, further efforts to evaluate the palaeotemperature record from the Gulf of Mexico are clearly warranted. These palaeoclimatic studies will have to be augmented by additional climate model experiments to understand the sensitivity of the global climate system to deglacial changes in boundary conditions. Our present simulations, however, support a scenario through which the climate system (via the melting history of the Laurentide Ice Sheet) could have transformed relatively gradual and monotonic astronomical forcing into a series of abrupt, non-monotonic climate changes over a large part of the globe.

Cloning and sequencing of the complementary DNA for platelet-derived endothelial cell growth factor indicates that it is a novel factor distinct from previously characterized proteins. The factor, a protein with a relative molecular mass of about 45,000, stimulates endothelial cell growth and chemotaxis *in vitro* and angiogenesis *in vivo*.

PLATELET-DERIVED endothelial cell growth factor (PD-ECGF) is an endothelial cell mitogen of relative molecular mass ( $M_r$ ) ~45,000 (45K) purified to homogeneity from human platelets<sup>1,2</sup>. By contrast with other endothelial mitogens of the fibroblast growth factor (FGF) family (reviewed in refs 3 and 4), PD-ECGF, which seems to be the only endothelial cell growth factor in human platelets<sup>2</sup>, does not bind to heparin and does not stimulate the proliferation of fibroblasts<sup>1</sup>. We describe here the protein sequencing, cDNA cloning and expression of functionally active PD-ECGF. In addition, we show that PD-ECGF has chemotactic activity for endothelial cells *in vitro* and angiogenic activity *in vivo*.

## Sequence of PD-ECGF

Information about the protein sequence of PD-ECGF was obtained by the N-terminal sequencing of intact PD-ECGF, and by analysing the fragments obtained after digestion with trypsin, staphylococcal V8 protease, or CNBr (Fig. 2).

To localize a source of production of PD-ECGF, a specific

antisera against PD-ECGF (ref. 2) was used to screen cell lines and tissues by immunoblotting. A strong 45K band was found when extract from a term placenta was analysed (data now shown). A cDNA library was therefore constructed in  $\lambda$ gt10 using poly(A)<sup>+</sup> RNA from human placenta, and screened with oligonucleotide probes constructed using the information from the protein sequencing; the screening of  $3 \times 10^5$  clones yielded three positive clones.

Nucleotide sequencing of the 1.8-kilobase (kb) insert of one of the clones (APL8) revealed a short GC-rich 5' untranslated region, an open reading frame predicting the translation of a 482-residue protein ( $M_r$  49,972), and a short 3' untranslated sequence containing a poly(A)<sup>+</sup> tail (Fig. 1). The translation is probably initiated by the ATG start codon at nucleotides 124-126, as the surrounding nucleotide sequence follows the rules for translation initiation<sup>3</sup>, whereas the sequence surrounding ATG at nucleotides 136-138 does not. Furthermore, there are no other ATG codons between an in-frame stop codon at nucleotides 28-30 and the nucleotides coding for the N-terminus of intact PD-ECGF (Fig. 2). A stop codon (TAA) is present at nucleotides 1,570-1,572, and is part of the polyadenylation signal (nucleotides 1,568-1,573). Fourteen nucleotides downstream of this signal, a long stretch of poly(A)<sup>+</sup> was found. A similar overlap of the stop codon and the polyadenylation signal has been reported for human choriongonadotropin B-chain<sup>6</sup>.

Of the 482 amino-acids of PD-ECGF deduced from the cDNA clone, 389 were identified by amino-acid sequencing (Fig. 2). The N-terminal sequence of PD-ECGF starts 10 amino acids downstream of the proposed translation initiation site, indicating that the molecule undergoes a limited proteolytic processing after synthesis. The C-terminal amino acids predicted from the

§ To whom correspondence should be addressed.

cDNA sequence, except the last four, were identified by amino-acid sequencing. It is not known whether PD-ECGF undergoes proteolytic processing in the C-terminus, if so, a maximum of four amino acids are removed. The  $M_r$  of the mature protein would thus be 48.6–49K, in reasonable agreement with the estimate of 45K obtained from SDS-gel electrophoresis of pure PD-ECGF<sup>1,2</sup>.

The predicted amino-acid sequence from the cDNA clone matched the previously obtained amino-acid sequence except

at position 471, where the nucleotide sequence predicts Leu, whereas Ser was found in both of two different peptides obtained from this region (Fig. 2). It is possible that polymorphism occurs at this position.

Matching the sequence of PD-ECGF with those of the PIR, EMBL and Genbank databases (releases 17, 14 and 56, respectively) revealed no striking similarities to other proteins. Short internal repeats in the sequence were noted (overlined in Fig. 2). One important feature of the sequence is the lack of a

FIG. 1 Nucleotide sequence of PD-ECGF. The putative initiation codon is at nucleotides (nt) 124–126. An in-frame stop codon (nt 28–30) upstream of the initiation codon is marked with dots and a stop codon at nt 1,570–1,572 with an asterisk. The polyadenylation signal (nt 1,568–1,573) is underlined with an arrow. Regions corresponding to the prepared oligonucleotide probes 228, 231, 240, 258 and 259, are underlined.

**METHODS.** Total RNA was isolated from a human placenta of 22-gestational-weeks by the method of Han *et al.*<sup>21</sup>. A cDNA library was constructed in  $\lambda$ gt10 from the poly(A)<sup>+</sup> RNA following the method described by Watson *et al.*<sup>22</sup> with some modifications: following the first strand synthesis, oligo(dG) was added to its 3' end by terminal transferase; second strand synthesis was primed by addition of an external primer of oligo(dC), as well as internal RNA primers made by RNaseH. Five unique oligonucleotides were deduced from the amino-acid sequence by the method of Lathe<sup>23</sup> and prepared by an Applied Biosystems DNA synthesizer 381A. The oligonucleotide probes were labelled by end-tailing or primer extension. Independent clones (~300,000) from the human placenta  $\lambda$ gt10 cDNA library were screened with these probes separately following the method described by Ullrich *et al.*<sup>24</sup>. Three clones were found to be positive both with probes 228 and 240. The cDNA inserts were shown to be colinear by restriction mapping. The cDNA insert of  $\lambda$ PL8, with the longest insert of ~1.8 kb, was subcloned into M13mp18 and Bluescript (Stratagene). Deletion mutants were made by the sequential deletion method of Yanisch-Perron *et al.*<sup>25</sup>. Both strands of the cDNA were sequenced by the dideoxy-termination method<sup>26</sup>. Sequences that were difficult to determine by this procedure were examined by the Maxam-Gilbert method<sup>27</sup>.

FIG. 2 Amino-acid sequence of PD-ECGF (one-letter code). N-terminal sequence (—), tryptic fragments (---), staphylococcal protease V8 fragments (---) and a CNBr fragment (====) of PD-ECGF are indicated, as well as Cys residues (\*), a potential N-glycosoylation site (■), and a possible site of polymorphism (▲). Internal repeats are overlined.

**METHODS.** To prepare tryptic fragments, 40  $\mu$ g pure PD-ECGF<sup>2</sup> was desalted on a C4 narrow-bore reversed-phase column (Brownlee Aquapore BU-300; 2.1  $\times$  30 mm), eluted with 0.1% trifluoroacetic acid and a gradient of acetonitrile, and then dried in a Speedvac Concentrator and redissolved in 200  $\mu$ l 6 M guanidine-HCl, 0.25 M Tris-HCl, pH 8.5, 1 mM EDTA, containing 100  $\mu$ g dithiothreitol. The solution was flushed with N<sub>2</sub> for 20 s and left at room temperature for 3 h, at which time 2  $\mu$ l 4-vinyl-pyridine was added. After a further 3 h at room temperature, the sample was desalted by chromatography on the C4 column. The volatile solvent was removed as above and PD-ECGF was digested with TPCK-trypsin (Sigma; substrate/enzyme ratio, 50 (w/w)) in 0.1 M ammonium bicarbonate, containing 2 M urea, for 4 h at 37°C. The tryptic fragments were immediately loaded onto a C4 narrow-bore, reversed-phase HPLC column eluted with a linear gradient of acetonitrile in 0.1% trifluoroacetic acid. Non-homogeneous peptides were re-run on HPLC narrow-bore reversed-phase column under different conditions. The column temperature was kept at 35°C, the flow rate was 100  $\mu$ l min<sup>-1</sup> and the effluents were monitored at 220 nm. Fractions were collected manually in polypropylene tubes. Peptides were also isolated from PD-ECGF fragmented with staphylococcal V8 protease or CNBr

by similar methods. The amino-acid sequences of the peptides were determined by use of an automated gas-phase sequencer (Applied Biosystems Protein sequencer, model 470A, with an online PTH-analyser, model 120A).

hydrophobic signal sequence, suggesting that PD-ECGF is not a classical secretory protein. The sequence contains only one Tyr, which is probably not exposed on the surface of the molecule, as attempts to radiolabel PD-ECGF with  $^{125}\text{I}$  using the chloramine-T method resulted in a very low incorporation of radioactivity<sup>2</sup>. There is one potential *N*-glycosylation site, Asn 63. The PTH-amino-acid yield of the corresponding tryptic peptide decreased dramatically, just before this residue (Fig. 2). This could be due to the formation of a cyclic compound of the Asn residue and the following Gly residue<sup>7</sup>, which can occur only if the Asn residue is non-glycosylated. This, in combination with the  $M_r$  of PD-ECGF as determined by SDS-gel electrophoresis, compared with the  $M_r$  predicted from the cDNA clone, indicates that Asn 63 is not glycosylated. There are a total of seven Cys residues, indicating that the molecule contains at least one free thiol group.

### Southern and northern blotting

To obtain information about the structure of the human PD-ECGF gene, Southern blotting analysis of human DNA was performed. Hybridization with a PD-ECGF cDNA probe revealed single bands of 19 kb and 9.2 kb after digestion with *Hind*III and *Xba*I, respectively (Fig. 3a). This indicates that only one copy of the PD-ECGF gene is present in the human genome. Indeed, analysis of human genomic PD-ECGF clones supports this conclusion (K.H. *et al.*, manuscript in preparation). Human placenta poly(A)<sup>+</sup> RNA was examined by northern blotting; a single transcript of about 1.8 kb was recognized by the PD-ECGF cDNA probe (Fig. 3b). As the longest cDNA clone found,  $\lambda$ PL8, has an insert of about 1.8 kb, it probably represents a full-length copy of the PD-ECGF transcript.

### Expression of PD-ECGF cDNA

To verify the authenticity of the cDNA clone, it was expressed in NIH 3T3 cells. The  $\lambda$ PL8 insert was subcloned into the pLJ expression vector to give pLPL8J. This vector has Molony leukaemia virus long terminal repeat as a promoter to drive the cDNA transcription, as well as a neomycin-resistance gene as a selection marker<sup>8</sup>. pLPL8J and pLJ were introduced into the NIH 3T3 cells by the calcium phosphate co-precipitation method, and cell lines were selected by neomycin. Analysis of one cell line transfected with pLPL8J revealed growth-promoting activity for porcine aortic endothelial cells in the cell lysate, but not in the conditioned medium (Fig. 4a,b). The activity was completely neutralized by a specific rabbit antiserum against PD-ECGF, indicating that the activity was due to the synthesis of functionally active PD-ECGF by the cell line (Fig. 4a). The NIH 3T3 cell line transfected with only the pLJ vector did not contain any growth-promoting activity for porcine aortic endothelial cells. Furthermore, the cell lysate of the cell line transfected with pLPL8J was found to contain a 45K component in immunoblotting experiments in which the antiserum against PD-ECGF was used (Fig. 4c). The size of the product was similar to that of human PD-ECGF purified from platelets (Fig. 4c). These data show that the purified, sequenced and cloned PD-ECGF molecule is responsible for the observed biological effect on porcine endothelial cells. That PD-ECGF produced by the transfected NIH 3T3 cells remained inside the producer cells and was not secreted to any appreciable extent into the cell culture medium, is consistent with the lack of a signal sequence in the protein (Fig. 1). This is a property that PD-ECGF shares with acidic FGF (ref. 9) and basic FGF (ref. 10). It is not known whether there are alternative mechanisms to release these factors from their producer cells.

### Chemotactic activity of PD-ECGF

PD-ECGF was found to have a chemotactic effect on bovine aortic endothelial cells, with half-maximal activity at about  $1 \text{ ng ml}^{-1}$  (Fig. 5a). Consistent with its mitogenic target cell specificity for endothelial cells, PD-ECGF did not induce

smooth muscle cell migration. Controls using serum- and platelet-derived growth factor induced extensive smooth-muscle-cell migration in the same experiment. Checkerboard analysis revealed that endothelial cell migration induced by PD-ECGF was due to directed cell migration (chemotaxis) and not to random migration (chemokinesis) (Fig. 5b). The chemotactic activity of PD-ECGF was neutralized by PD-ECGF antibodies (Fig. 5c).

### Angiogenic activity of PD-ECGF

Two different approaches were taken to investigate whether PD-ECGF has angiogenic activity *in vivo*. First, we investigated the effect of PD-ECGF on the developing vascular system of the chick chorioallantoic membrane. Partially purified PD-ECGF consistently induced a strong angiogenic response (Fig. 6a), which was inhibited by antibodies against PD-ECGF (Fig. 6b). Thus, the angiogenic response is unlikely to be due to inflammation or other factors than PD-ECGF present in the preparation. Furthermore, pure PD-ECGF, at a dose of 50 ng, induced angiogenesis in the chorioallantoic membrane (data not shown).

Second, we investigated the effect of transfection of PD-ECGF cDNA into tumour cells on the vascularization of tumours formed by these cells in nude mice. NIH 3T3 cells transformed by an activated human *Ha-ras* gene<sup>11</sup> (termed a1-1 cells) were chosen as target cells and were transfected with a plasmid containing PD-ECGF DNA (pLPL8J), or with a control plasmid without insert (pLJ). After transfection, cells were selected by G418 resistance, and then injected subcutaneously into nude mice. After 2 weeks, tumours had grown to ~2 cm in diameter from both cell types; they were then collected and fixed in formaldehyde. A histological examination revealed that the tumours that developed from a1-1 cells, transfected with

FIG. 3 a, Southern blot analysis of *Hind*III (lane 1) or *Xba*I (lane 2) digests of human DNA. b, Northern blot analysis of poly(A)<sup>+</sup> RNA from human placenta. Migration positions of ribosomal RNA markers are shown on the left. Blots were hybridized with PD-ECGF cDNA probes.

**METHODS.** High-molecular weight human genomic DNA was prepared from normal human leukocytes. Samples of  $10 \mu\text{g}$  each were digested by restriction enzymes, subjected to electrophoresis in agar and blotted on to nitrocellulose membranes (Schleicher and Schüll). Poly(A)<sup>+</sup> RNA ( $1 \mu\text{g}$ ), purified from human placenta of 22 weeks' gestation as described in the legend to Fig. 1, was electrophoresed in a 0.9% formalin-denaturing gel and blotted on to Hybond-N nylon filter (Amersham). Hybridization was performed in a solution of 50% formamide, 0.65 M NaCl, 0.1 M sodium PIPES, pH 6.8, 10% dextran sulphate,  $5\times$  Denhardt's solution, 0.1% SDS, 4 mM EDTA and  $100 \mu\text{g ml}^{-1}$  salmon sperm DNA at  $42^\circ\text{C}$  for 18 h, and then washed four times with  $2\times\text{SSC}$ , 0.2% sodium phosphate, 0.1% SDS for 20 min periods at  $50^\circ\text{C}$ .

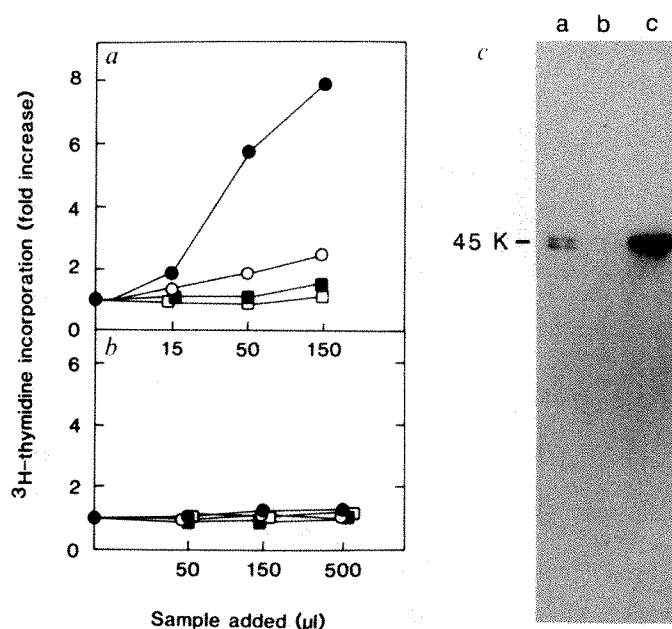

pLPL8J, contained a very high density of blood vessels (Fig. 6c), by contrast with tumours from a1-1 cells transfected with pLJ without cDNA insert, which contained only a few blood vessels (Fig. 6d). In conclusion, PD-ECGF has a potent angiogenic activity both in the chorioallantoic membrane assay and when expressed by tumour cells growing in nude mice.

## Discussion

Angiogenesis is an important process during, for example, embryogenesis, wound healing and organ regeneration. In addition, aberrant angiogenesis occurs in several pathological conditions, such as in tumour growth, in certain retinopathies, and in rheumatoid arthritis. Angiogenesis is a complex process that involves several steps, including migration and proliferation of endothelial cells<sup>12</sup>. The best characterized of the factors that

have been found to stimulate angiogenesis are FGFs, a family of heparin-binding endothelial cell mitogens that were originally purified from neural tissues<sup>3,4</sup>. Additionally, transforming growth factor (TGF)- $\alpha$ <sup>13</sup>, TGF- $\beta$ <sup>14,15</sup>, tumour necrosis factor- $\alpha$ <sup>16,17</sup> and angiogenin<sup>18</sup> have been found to have angiogenic activity. PD-ECGF, acidic and basic FGFs, and TGF- $\alpha$  are the only factors that have been shown to stimulate endothelial cells both *in vitro* and *in vivo*<sup>3,4,13</sup>. The target cell specificities of these factors, however, differ: FGFs and TGF- $\alpha$  stimulate proliferation of a wide variety of cells including fibroblasts, whereas PD-ECGF so far has not been found to stimulate any cell type other than endothelial cells. Furthermore, the deduced primary structure of PD-ECGF shows no similarity with other known proteins. Thus, the biological and structural properties of PD-ECGF indicate that it is a novel type of angiogenic factor that

FIG. 4 Biosynthesis of PD-ECGF in NIH 3T3 cells transfected with pLPL8J. Growth factor activity from a cell lysate (a) and the conditioned medium (b) of NIH 3T3 cells, transfected with PD-ECGF cDNA (NIH3T3-pLPL8J; circles) or with the corresponding vector without insert (NIH3T3-pLJ; squares) in the absence (filled symbols) and presence (open symbols) of PD-ECGF antibodies<sup>2</sup>. PD-ECGF protein was also visualized by immunoblotting using PD-ECGF antiserum (c); lane a, PD-ECGF purified from human platelets; lane b, cell lysate for NIH 3T3-pLJ cells; lane c, cell lysate from NIH3T3-pLPL8J cells. **METHODS.** NIH 3T3 cells transfected with pLJ or with pLPL8J were grown to confluence in 10-cm cell-culture dishes in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% calf serum and antibiotics. The cells were then cultured for 24 h in serum-free conditions in DMEM supplemented with 1% bovine serum albumin, 7.8  $\mu\text{g ml}^{-1}$  cholesterol, 5.5  $\mu\text{g ml}^{-1}$  oleic acid, 8  $\mu\text{g ml}^{-1}$  L- $\alpha$ -phosphatidylcholine and 0.2  $\text{mg ml}^{-1}$  transferrin. After collecting the conditioned media, cells were washed twice in PBS and then scraped into 1 ml PBS. Following careful resuspension, a cell lysate was prepared by disrupting the cells by three cycles of freezing and thawing, followed by centrifugation at 25,000g for 30 min and collection of the supernatants. Growth-promoting activity was measured by the incorporation of <sup>3</sup>H-thymidine into porcine aortic endothelial cells<sup>1</sup> in the absence or presence of 2  $\mu\text{g ml}^{-1}$  PD-ECGF antibody purified by protein A-Sepharose<sup>2</sup>. For immunoblotting, cell lysates were prepared by washing and resuspending the cells in PBS containing 1 mM phenylmethylsulphonyl fluoride (Sigma), 150 KIU aprotinin (Sigma) and 10 mM EDTA. The lysates and 100 ng pure PD-ECGF<sup>2</sup> were subjected to SDS-gel electrophoresis in 10–18% gradient polyacrylamide gel under reducing conditions<sup>28</sup>. After transfer to a nitrocellulose membrane, immunoblotting was performed as described<sup>29</sup>, using a 1:50 dilution of PD-ECGF antiserum<sup>2</sup>. <sup>125</sup>I-labelled staphylococcal protein A, bound to antibodies on the blot, was visualized by autoradiography. PD-ECGF

purified from platelets occurs as a doublet of about 45K, probably as a result of proteolysis during preparation<sup>2</sup>.

FIG. 5 Chemotactic activity of PD-ECGF. a, The migration of bovine aortic endothelial cells (BAEC; closed circles and left ordinate) and smooth muscle cells (SMC; open circles and right ordinate) towards different concentrations of PD-ECGF. Controls are shown as a histogram: I, BAEC medium only; II, BAEC medium plus 10 ng ml<sup>-1</sup> basic FGF; III, SMC medium only; IV, SMC medium plus 5% FCS. b, Checkerboard analysis of BAEC migration. The data represent cell number per field (%). Standard deviations were below 15%. The values below the diagonal indicate chemotaxis. c, The chemotactic activity of PD-ECGF is neutralized by PD-ECGF antibodies: 1, buffer control; 2, pure PD-ECGF (5 ng ml<sup>-1</sup>); 3, pure PD-ECGF (5 ng ml<sup>-1</sup>) and anti-PD-ECGF

antibodies (300 ng ml<sup>-1</sup>) (purified by protein A-Sepharose).

**METHODS.** Chemotaxis assays of BAEC and SMC were performed in 48-well microchambers as described<sup>30</sup>. Gelatin and fibronectin coating of the Nucleopore filters was necessary for BAEC adhesion. Cells (18,000 BAEC or 25,000 SMC per well) were added to the upper wells. Serum-free DMEM was used for SMC migration, and DMEM supplemented with 1% FCS for BAEC migration. The number of cells that had migrated during a 5 h incubation period to the lower surface of the filter were counted in three high-power fields. All experiments were done in triplicate.

FIG. 6 Angiogenic properties of PD-ECGF. *a*, and *b*, The induction of angiogenesis in the chick chorioallantoic membrane. *a*, Partially purified PD-ECGF (purified through the hydroxylapatite step<sup>2</sup>, 1% pure, 1.2 mg of protein ml<sup>-1</sup>; 5  $\mu$ l per methylcellulose disk) induced angiogenesis on the chick chorioallantoic membrane (89% positive results,  $n$ (number of embryos)=65). *b*, Partially purified PD-ECGF incubated for 20 min with anti-PD-ECGF antibodies (2.5  $\mu$ l each solution) (59% negative results,  $n$ =22). In addition, 50 ng pure PD-ECGF induced angiogenesis (93% positive results,  $n$ =15). Test substances were incorporated into methylcellulose disks (10  $\mu$ l) and transplanted onto 9-day-old chorioallantoic membranes as described<sup>31,32</sup>. The assays were analysed daily for 2 days. Disks were visible by their light reflections. *c* and *d*, The angiogenic effect of PD-ECGF after

expression by tumour cells growing in nude mice. a1-1 cells were transfected with pLJ (control) or pLPL8J (carrying a PD-ECGF insert) by electroporation (Biorad, Gene Pulser). Transfected cell clones were selected by G418 resistance. All a1-1 clones transfected with pLPL8J were found to have growth-promoting activity on porcine aortic endothelial cells, which could be inhibited by PD-ECGF antibodies (data not shown); a1-1 cells transfected with pLJ had no such activity. a1-1 cells transfected with pLPL8J (*c*) and cells transfected with pLJ (*d*) were injected subcutaneously at a cell number of  $1 \times 10^5$  into nude mice and tumours of ~2-cm diameter developed in ~2 weeks. Tumours were collected, fixed with formaldehyde, stained with hematoxylin-eosin and examined with light-microscope. The photographs represent an 825-fold magnification.

may act specifically on endothelial cells. The finding that PD-ECGF is present in the placenta is intriguing, since angiogenesis is an important process in the development of this organ.

The restricted target cell specificity of PD-ECGF and the fact that platelets are a main source of it, suggest that PD-ECGF has a role in maintaining the integrity of the blood vessels. After injury to the endothelial cell layer of vessels, platelets aggregate at the subendothelial space. Platelet-release products, such as platelet-derived growth factor, are thought to be involved in the development of atherosclerotic lesions by stimulating migration and proliferation of smooth muscle cells and fibroblasts in the arterial media<sup>19,20</sup>. Although the precise mechanism of secretion of PD-ECGF is not known at present, it is possible that PD-ECGF counteracts the atherogenic effect of other platelet products by promoting repair of the endothelial cell layer. The availability of functionally active recombinant PD-ECGF (Fig. 4), combined with a high yield purification method<sup>2</sup>, cDNA clones (Fig. 1) and specific antibodies<sup>2</sup>, now makes it possible to address questions related to the function of PD-ECGF *in vivo*. □

THE distances and velocities of 400 elliptical galaxies<sup>1</sup>, out to redshifts equivalent to recession velocities of  $\sim 6,000 \text{ km s}^{-1}$ , suggest that the peculiar velocities obtained by subtraction of the general cosmological expansion are best fitted by a flow induced by a 'great attractor'<sup>2</sup>, a large mass of  $5.4 \times 10^{16} M_{\odot}$  and centred on galactic longitude  $l = 307^{\circ}$  and latitude  $b = 9^{\circ}$  at a distance  $R_m = 4,350 \pm 350 \text{ km s}^{-1}$ . A redshift survey of  $\sim 900$  galaxies<sup>3</sup> shows that the excess galaxy number counts in this direction are due to two substantial concentrations of galaxies at recession velocities  $v \approx 3,000 \text{ km s}^{-1}$  and  $4,500 \text{ km s}^{-1}$ . Here we show that in roughly the same direction there is also a very rich concentration of galaxy clusters which may have a considerable dynamical influence. The estimated redshift distances of these clusters range from  $3,000$  to  $20,000 \text{ km s}^{-1}$ , with a main complex at  $v \approx 14,000 \text{ km s}^{-1}$ . The barycentre of this concentration lies  $\sim 25^{\circ}$  away from the cosmic microwave background dipole<sup>4</sup>, and  $\sim 10^{\circ}$  away from the latest reported position of the Great Attractor<sup>5,6</sup>.

The distribution of clusters of galaxies is of fundamental significance in understanding the matter distribution, in explaining the origin of the observed peculiar velocity field<sup>7,2</sup>, and in estimating both the local peculiar acceleration vector and the distance at which the Hubble flow becomes unperturbed<sup>8</sup>. Although their number is relatively small, the clusters, being peaks of the density field, might avoid the problems that some other all-sky density tracers (for example, IRAS galaxies<sup>9–12</sup>) have in describing the large-scale density field.

We have analysed the southern part of the new Catalogue of Rich Clusters of Galaxies<sup>13</sup> (hereafter ACO), which lists 1,638 clusters with declination  $\delta \leq -17^{\circ}$ . This catalogue lists redshifts for 145 clusters. The incompleteness of the sample with respect to redshift means that, contrary to what has been done in the Northern Hemisphere<sup>14</sup>, it is not sufficient to use those few clusters with known velocity to map the large-scale distribution of clusters in the Southern Hemisphere. We have therefore used 143 redshifts ( $z$ ) to estimate a linear relation between  $\log [D_L(z)] + 0.2K(z)$  and the magnitude of the tenth brightest member, including also a correction for the cluster richness (Scott effect). Here,  $D_L(z)$  is the luminosity distance, assuming cosmological deceleration  $q_0 = 1/2$ , and  $K(z)$  is the K-correction for E and S0 galaxies<sup>15</sup>. We find that the relation has a dispersion

$\sigma_{\text{sample}} \approx 0.11$  in  $\log [D_L(z)] + 0.2K(z)$ , corresponding to  $\Delta z/z \approx 0.25$  for small  $z$ . In deriving this relation, two clusters have been excluded because their redshift appeared to be inconsistent (beyond three standard deviations) with the magnitude given in the catalogue. Hereafter co-moving distances  $d = D_L(z)/(1+z)$  will always be scaled by the value of  $H_0 = 100 \text{ km s}^{-1} \text{ Mpc}^{-1}$  and quoted in  $\text{km s}^{-1}$ .

A preliminary identification of candidate superclusters was made using a percolation algorithm on the reference catalogue, that is, the catalogue with distances  $d = \langle d \rangle$ , where the average is derived from a gaussian distribution in  $\log [D_L(z)] + 0.2K(z)$  with variance  $\sigma_{\text{sample}}^2$ . The statistical robustness of these structures was verified on 100 random catalogues in which the estimated redshift for each cluster was drawn according to the previous distribution.

A detailed description of the  $z$  estimates and of the supercluster candidates from the ACO catalogue, as well as of their robustness and membership, will be given elsewhere (R.S. *et al.*,

Clusters with identification no. in boldface have measured redshifts listed in the ACO catalogue. After this work was completed, we found measured redshifts<sup>26</sup> for four of the clusters with distance estimates. The measured values and the estimated ones are in agreement within the errors.

\* Clusters tentatively belong to the main complex cited in the text (value of the percolation radius  $R = 1,500 \text{ km s}^{-1}$ ).

manuscript in preparation). Of course, because of the uncertainty in our distance estimates, some numerical details in the following discussion may change after observed redshifts become available.

A remarkable concentration<sup>16</sup> of clusters in the direction of Centaurus is clearly evident in Fig. 1, which shows an all-sky projection of all the ACO and Abell clusters with a measured or estimated distance  $< 20,000 \text{ km s}^{-1}$ . We have derived an estimate of the overdensity of clusters in this region, which we call the  $\alpha$ -region, in the following way. The ACO catalogue covers 1.38 steradian in the latitude range  $20^\circ \leq |b| \leq 40^\circ$ . In this area it contains 96 clusters up to a distance of  $25,000 \text{ km s}^{-1}$ . Subtracting the number of clusters and the corresponding volume of the  $\alpha$ -region (28 clusters in 0.11 steradian up to a distance of  $20,000 \text{ km s}^{-1}$ ), we retain 68 clusters in a volume of  $\sim 7 \times 10^6 h^{-3} \text{ Mpc}^3$ , corresponding to a density of  $\sim 1 \times 10^{-5} h^{-3} \text{ clusters Mpc}^{-3}$ . This would imply an expected number of 2.9 clusters in the  $\alpha$ -region, corresponding to an observed overdensity of about a factor of 10 with respect to the mean volume density of all the other ACO clusters at a comparable galactic latitude (see Fig. 2). A possible source of error in the determination of the mean volume density of clusters (in addition to the statistical error which amounts to  $\sim 12\%$ ) could, in principle, derive from an incompleteness of the catalogue near the edge of the volume that we have used. We are, however, confident that this introduces only a minor uncertainty in our estimate, for two reasons. First, it is claimed<sup>13</sup> that the ACO catalogue is "nominally complete to  $z = 0.2$  for clusters with populations of 30 or more galaxies in the magnitude range  $m_3$  to  $m_{3+2}$ "; second, an analysis of the density of the ACO clusters as a function of distance (R.S. *et al.*, manuscript in preparation) shows that, after excluding the clusters in the  $\alpha$ -region, there is no evidence of a significant decrease of the density of clusters with richness  $R \geq 0$  up to at least  $R = 30,000 \text{ km s}^{-1}$ . In fact, similar values for the mean density of clusters are derived by using the volumes within  $R = 30,000 \text{ km s}^{-1}$  (130 clusters) or  $R = 35,000 \text{ km s}^{-1}$  (190 clusters).

As seen in Fig. 2, the distribution with depth of the clusters in the  $\alpha$ -region is not uniform, but is peaked at  $\langle d \rangle \approx 4,000 \text{ km s}^{-1}$  and at  $\langle d \rangle \approx 14,000 \text{ km s}^{-1}$ . The complex formed by the clusters denoted by '\*' among those listed in Table 1, appears to be worthy of future, detailed study. This candidate supercluster consists of a number of members similar to that of the Corona Borealis supercluster<sup>17</sup>, but has the advantage of being almost two times closer and two times more dense in clusters with richness  $R \geq 1$  than the Corona Borealis supercluster.

We are wary of using the spherical infall model to estimate the possible dynamical influence of the listed clusters, and have computed the peculiar acceleration,  $A_p$ , induced on the Local Group (LG) by the clusters listed in Table 1 according to  $A_p = A - \langle A \rangle$ . Here  $\langle A \rangle$  is the acceleration expected from the mean density of clusters in the same volume. It amounts to  $< 10\%$  of  $A$ , the acceleration induced on the LG by the observed clusters, which has been computed as<sup>18</sup>  $A = G \sum_i M_i \hat{r}_i / r_i^2$  where the mass of each cluster ( $M_i \equiv M_{R=2}(N_i^{\text{gal}}/106)$ ) is weighted by the number of galaxies in the cluster,  $N_i^{\text{gal}}$ , and is expressed in terms of the typical values of an  $R=2$  Abell cluster (that is, Coma, for which  $N_i^{\text{gal}} = 106$ ). We also have to assume pure Hubble flow for the proper distance,  $r_i = d_i H_0 / (1+z)$ , and obviously this can introduce systematic errors because of the presence of coherent peculiar flows.

About half the total computed acceleration is due to the nearest chain of four clusters ( $\langle d \rangle \approx 4,000 \text{ km s}^{-1}$ , consistent with the quoted distance of the Great Attractor) and the rest is due to the combined pull of the more distant complexes (see Fig. 2), which are dominated by the one at  $\langle d \rangle \approx 14,000 \text{ km s}^{-1}$  (eleven clusters denoted by '\*' in Table 1). This could help explain part of the 'large' peculiar velocity of the Centaurus cluster<sup>6</sup> and is consistent with the present lack of detection<sup>2</sup> of a reversed sign for the peculiar flow beyond  $4,500 \text{ km s}^{-1}$ . From 1,000 simulations, in which the estimated redshifts of the clusters were randomized around their nominal value, the standard error on the positively skewed distribution of the modulus of  $A$  is  $\leq 5\%$  whereas, given our narrow cone region, the direction

FIG. 1 Equi-area projection in right ascension ( $\alpha$ ) and declination ( $\delta$ ) of all the rich clusters with measured or estimated distances within  $20,000 \text{ km s}^{-1}$ . Triangles and squares represent Abell and ACO clusters respectively (some clusters are listed in both catalogues). The star shows the direction of the cosmic microwave dipole<sup>4</sup>, the empty circle shows the

latest direction of the Great Attractor<sup>5,6</sup>, and the empty hexagon shows the direction of the peculiar flow<sup>7</sup>. Between the latter two symbols the cluster concentration discussed in the text is clearly visible. Dashed lines indicate the avoidance zone due to the galactic plane ( $|b| \leq 20^\circ$ ).

almost coincides with the clusters' barycentre, being always within one degree from right ascension  $\alpha = 13^{\text{h}}26^{\text{m}}$  and  $\delta \approx -33^\circ$ . This agrees very well with one ( $\alpha = 13^{\text{h}}20^{\text{m}}$ ,  $\delta = -33^\circ$ ) of the possible directions for the Supergalactic Centre<sup>2</sup>. It is also close to a previously reported quadrupolar distortion of the peculiar flow<sup>19</sup>, while most of the optical dipole signal is due to a patch of sky also centred on the same zone<sup>20</sup>. Indeed, although the close agreement of the latter dipole with that of the cosmic microwave background favours a 'local' (within  $\sim 4,000 \text{ km s}^{-1}$ ) convergence of the peculiar acceleration, its contribution to the infall towards Centaurus<sup>20</sup>,  $v_p^{\text{dip}} \sim 250 \text{ km s}^{-1}$ , seems to account for only half of the observed one, again in good agreement with our above estimate.

If we now make the extreme hypothesis that the component of our peculiar velocity,  $v_p \approx 570 \text{ km s}^{-1}$ , towards this direction is entirely due to the  $A_p$  derived above, by using the relation<sup>18</sup>  $v_p = \frac{2}{3} H_0^{-1} \Omega_0^{-0.4} A_p$ , we have

$$M_{(R=2)} \approx 5 M_{15} h^{-1} \left( \frac{\Omega_0}{0.2} \right)^{0.4} \left( \frac{v_p}{570 \text{ km s}^{-1}} \right) \quad (1)$$

where  $M_{15} \equiv 10^{15} M_\odot$ .

This shows that in an open universe it would be possible to ascribe the whole required peculiar velocity to the observed clusters if the mass overdensity of an  $R=2$  cluster were  $\sim 5 M_{15}$ . Recent estimates<sup>21</sup> give the mass of the Coma cluster as  $\leq 3 M_{15}$ . The mass required is undoubtedly high, but the nominal value from equation (1) can be significantly lowered if the overdensity of clusters reported here extends into the avoidance region (see Fig. 1), and if, because of the incompleteness at such low galactic latitudes, many more clusters are present in the region we consider; according to a probability law  $P(|b|) = 10^{[-0.3(\csc |b| - 1)]}$ , one is likely to have missed half of the clusters with  $20^\circ \leq |b| \leq 40^\circ$ . Moreover, the required mass is not simply the mass confined within the Abell radius, but may be associated with larger galaxy aggregates in which the clusters are embedded, as suggested by the galaxy-cluster cross-correlation<sup>22,23</sup>. Similarly, if we divide the mass estimates<sup>17</sup> for the Corona Borealis Supercluster,  $M_{\text{SC}} \approx 26 M_{15}$ , by the number of members ( $N_{\text{cl}} = 6$  and weighted as above by the number of galaxies<sup>24</sup>) we obtain  $M_{(R=2)} \approx 6.6 M_{15}$ , which is in good agreement with the value derived from equation (1). Of course, this is not the end of the game because a biased distribution of matter would not be consistent with our assumption of clusters as tracers of the mass distribution, although recent estimates<sup>25</sup> seem to indicate a global biasing factor not very far from unity. A value of  $\Omega_0 = 1$  could still be made consistent with the constraints found from equation (1) either by boosting the estimate for  $M_{(R=2)}$  or, more realistically, by not requiring that the peculiar velocity be entirely due to a 'forward' gravitational pull. Underdensities and other great, comparable aggregates (Perseus-Pisces, or another new candidate supercluster similar to the one we present here but at larger distance (R.S. *et al.*, manuscript in preparation)) may have significant dynamical influences.

No definite conclusions can be drawn without a more complete picture of our surroundings. It would be of great interest to determine whether clusters of galaxies are partly responsible for the overall dynamics or, more unlikely, if we are led to infer the existence of very large mass condensations<sup>2</sup> ( $M_{\text{GA}} \approx 54 M_{15}$ ) in which no very rich clusters are seen<sup>3</sup>. This, if not attributed to highly specific initial conditions, might imply the existence of a physical process which would have coherently prevented cluster—but not galaxy—formation on scales of  $50\text{--}100 h^{-1} \text{ Mpc}$ .

Detailed study of this region is very important, not only because no similar nearby concentration of clusters exists elsewhere, but also because of its direction. It is hard to interpret as a mere coincidence the fact that such a concentration of clusters of galaxies is so close in the sky to both the direction of the cosmic microwave background dipole and that derived

FIG. 2 Distribution in distance of the 28 clusters from Table 1 (solid line). The short-dashed line shows their expected distribution if they were uniformly distributed. The long-dashed line shows the distribution expected from the average cluster density.

from the peculiar motions of galaxies with respect to the Hubble flow. But it must be said that the large-scale mass fluctuation necessary if the whole peculiar velocity is due to the clusters in Table 1 would be difficult to accommodate in many current cosmological models.

Further studies of clusters in this area with intrinsic distance estimates should eventually find the distance at which the peculiar flow reverses its sign, thus delineating the region which contains the bottom of a great potential well (assuming that this is the major cause of the reported peculiar velocities (A. A. Starobinsky, preprint)). The concentration discussed here appears to be the best candidate for the bottom of such a well because of both the number of clusters present and their particular richness. □

THE supernova SN1987A in the Large Magellanic Cloud has been observed by high-angular-resolution speckle interferometry since 25 March (30 days after the explosion) with the 4-m telescope at the Cerro Tololo Interamerican Observatory. These observations have provided a number of results that may be central to a detailed understanding of this unique event. Data obtained on 25 March and 2 April 1987 revealed a second bright 'companion' source separated from the supernova by 60 milliarcseconds and less than three magnitudes fainter than the supernova<sup>1</sup>. Measurements of the average diameter of the supernova envelope have been made from data recorded from March 1987 to April 1988<sup>2</sup>. Here we present a more detailed analysis of these data, which shows that the expanding envelope is asymmetric. This asymmetry has been observable since June 1987. The ratio between the minor and major axes of the envelope profile is about 2–3, and the position angle of the major axis is  $20^\circ \pm 5^\circ$ , consistent with results reported from polarization measurements. The major axis is aligned with the position angle of the companion to the supernova.

Speckle observations at optical wavelengths have been carried out using the PAPA detector<sup>3</sup>, a two-dimensional photon-counting sensor which records a catalogue of successive photon positions. The detector currently has a maximum data recording rate of 100,000 photons  $s^{-1}$  in a field of  $512 \times 512$  pixels. The speckle camera uses a fore-optics package which provides magnification of the image, so that the diffraction-limited scale of the telescope is matched to the pixel size of the camera, narrow-band optical filtering, which yields temporal coherence sufficient to allow interference over the path-length errors introduced by atmospheric aberrations, and atmospheric-dispersion correction, using a computer-controlled prism compensator. The digital output of the camera, in the form of photon addresses, is encoded on a video carrier and recorded with a VCR. The

stored addresses are recovered in the laboratory and unpacked for the speckle processing.

The photon addresses are grouped into frames, with a short time per frame relative to the atmospheric correlation time. This approach allows framing of the data for maximization of the signal-to-noise ratio in the integrated result; typical frame times range from 2 to 20 ms. Individual frames are built from the photon list by incrementing the number in the array position corresponding to the address of each detected photon. Corrections for the camera sensitivity (flat fielding) are made on the resulting frames. The Fourier transform for each frame is then calculated and accumulated into the power spectra and the complex correlation arrays which are required for diameter measurement and speckle image reconstruction using our version of the Knox-Thompson image-reconstruction algorithms<sup>4</sup>. Compensation for the atmospheric and telescope transfer function is accomplished by observing an unresolved comparison star immediately before and after the object observations. This star is chosen to be as close in angular position to the object as possible so that its atmospheric statistics are similar. Deconvolution by the reference star enhances the amplitudes of the high angular frequencies in the reconstruction. A detailed treatment of the algorithms and data processing is discussed elsewhere<sup>4</sup>.

Data sets on SN1987A and other stars result in diameter determinations with a precision of better than one milliarcsec. These measurements are made by fitting the integrated power spectra to the power spectrum of a uniform disk<sup>2</sup>, and, depending on the signal-to-noise ratio, can give results with resolution exceeding the diffraction limit of the telescope. Further analysis of the speckle data recorded between June 1987 (95 days after the explosion) and April 1988 (411 days after the explosion) shows that the expanding shell is elongated<sup>5</sup>. This asymmetry is detected from data recorded at several wavelengths between 442.0 nm and 850.0 nm. Figures 1a, c, e and g show the power spectra of SN1987A obtained from the data recorded near the centre of the H $\alpha$  emission line in May–June 1987, November 1987, February–March 1988 and April 1988. These power spectra are elongated, with a major axis corresponding to a position angle (PA) in image space of  $20^\circ$  (or  $200^\circ$ )  $\pm 5^\circ$ . Similar departures from circular symmetry are seen in the power spectra obtained from data recorded in several different wavelengths. By fitting the power spectra of uniform-brightness ellipses to the observed power spectra, we determined the lengths of the

FIG. 1 Speckle power spectra of SN1987A recorded in H $\alpha$  at four different epochs. (a, c, e, g) and ellipses showing schematically the size and orientation of the envelope at each epoch (b, d, f, h). a, b, June 1987; c, d, November 1987; e, f, February 1988; g, h, April 1988.

major and minor axes, and their position angles. All of the measurements gave the same PA within the error bars. A summary of the measurements is given in Table 1. In contrast, data recorded on comparison stars give symmetric power spectra and symmetric images with measured angular diameters of less than 3 mas.

The ratio of the minor to major axis of the supernova's envelope is about 2–3 for all four data sets. The apparently increasing asymmetry in the supernova's power spectra shown in Fig. 1 is due to the increasing angular size of the supernova relative to the telescope's diffraction limit. Figures 1*b*, *d*, *f* and *h* show the ellipses whose Fourier transforms are fitted to the power spectra at the various epochs.

True images of SN1987A and its comparison star,  $\nu$  Vol, were reconstructed using Knox–Thompson speckle-imaging techniques<sup>4</sup>. Figure 2 shows the images from data recorded in April 1988 at 533.0 nm (10-nm bandpass) and H $\alpha$  (10-nm bandpass). The elongation of the supernova images, along an axis inclined at a position angle of 20° (or 200°), is quite evident despite the fact that its angular size in April was only slightly greater than the telescope's diffraction limit. Because the size of the image was so close to the telescope diffraction limit, the size of the axes were determined from power spectra, not from reconstructed images. The images also appear to be somewhat brighter in the south-west direction. The  $\nu$  Vol images show no elongation and are symmetric. Their size is equivalent to the beam size for the reconstruction process.

In addition to our speckle results, other observations of SN1987A show strong evidence for an asymmetrically expanding shell<sup>6</sup>. Early spectroscopic observations (between 20 and 80 days after the explosion) detected a double-peaked feature in several hydrogen lines at optical and infrared wavelengths<sup>7–8</sup>. The appearance of two equally displaced components at longer and shorter wavelengths than the maximum emission was interpreted as being due to some departure from spherical symmetry of the shell.<sup>10</sup> Polarimetric observations<sup>11–14</sup> also show strong evidence for asymmetry in the envelope with a position angle of  $\sim 200^\circ$ . The observed polarization structure was interpreted as arising from an asymmetrically expanding, scattering atmosphere. Polarimetric data were modelled by a scattering atmo-

FIG. 2 Image reconstructions of SN1987A and a comparison star recorded in April 1988. *a*, SN1987A at 533.0 nm. *b*, Comparison star at 533.0 nm. *c*, SN1987A at H $\alpha$ . *d*, Comparison star at H $\alpha$ .

TABLE 1 Measured asymmetries for SN1987A (PA =  $200 \pm 5^\circ$ )

Days after explosion	$\lambda$ (nm)	Average diameter (mas)	Major axis (mas)	Minor axis (mas)
95–98 (May–June 87)	5,330	$18 \pm 2$	$19 \pm 2$	$17 \pm 2$
	6,565 (H $\alpha$ )	$8 \pm 1$	$10 \pm 2$	$6 \pm 2$
	7,750	$15 \pm 2$	$20 \pm 2$	$10 \pm 2$
265–268 (Nov. 87)	6,585 (H $\alpha$ )	$17 \pm 1$	$18 \pm 3$	$14 \pm 3$
	8,500	$16 \pm 1$	$20 \pm 2$	$14 \pm 2$
370–373 (Feb.–Mar. 88)	4,420	$25 \pm 2$	$27 \pm 2$	$22 \pm 2$
	5,330	$20 \pm 1$	$24 \pm 2$	$14 \pm 2$
	6,400	$17 \pm 1$	$20 \pm 2$	$15 \pm 2$
	6,565 (H $\alpha$ )	$21 \pm 1$	$24 \pm 2$	$16 \pm 2$
	7,000	$17 \pm 1$	$20 \pm 2$	$16 \pm 2$
	8,500	$18 \pm 2$	$25 \pm 2$	$12 \pm 2$
409–411 (April 88)	5,330	$26 \pm 2$	$30 \pm 2$	$20 \pm 2$
	6,565 (H $\alpha$ )	$27 \pm 1$	$30 \pm 2$	$20 \pm 2$
	8,500	$24 \pm 2$	$28 \pm 3$	$16 \pm 3$

sphere shaped as a prolate or oblate spheroid<sup>12,13,15</sup>. Best fits have been obtained for ratios of the smallest to the largest axis of these spheroids ranging from 0.6 to 0.9. Recently,  $\gamma$ -ray observations have yielded linewidths requiring either fragmentation or asymmetry of the supernova shell for their explanation<sup>16</sup>.

Present results from speckle interferometry, polarimetry, spectroscopy and  $\gamma$ -ray observations show that the expanding atmosphere of SN1987A is not spherically symmetric. The theoretical models that assume spherical symmetry must clearly be revised. An asymmetric envelope may also be necessary to explain, for example, the early emergence of X-rays and  $\gamma$ -rays and the evolution of their spectra with time<sup>17</sup>. Woosley<sup>18</sup> has suggested that non-uniformities in the collapse and core bounce could produce an asymmetric explosion, but that this asymmetry is far less likely to propagate to the outer envelope. Chevalier and Soker<sup>19</sup> have modelled the expanding supernova envelope and concluded that the most likely mechanism for asymmetry is rotational flattening of the progenitor envelope, probably requiring a binary companion during stellar evolution. Much of the evidence for asymmetries and extended structures around the supernova is summarized by Trimble<sup>20</sup>.  $\square$

ACKNOWLEDGEMENTS. We are grateful to R. Williams for granting us observing time on the CTIO 4-m telescope for this project and to the CTIO staff for their assistance. We thank R. Predmore for his help with elliptical fitting routines. This work has been partially supported by the Smithsonian Institution Scholarly Studies and Research Opportunities grant programs. L.K. is Visiting Scientist from CERGA, Grasse, France.

# Deuterium content of the Venus atmosphere

Jean-Loup Bertaux\* & John T. Clarke†

\* Service d'Aéronomie du CNRS, BP 3, 91371 Verrières le Buisson, France

† Department of Atmospheric, Oceanic and Space Science, University of Michigan, Ann Arbor, Michigan 48109, USA

THERE is no liquid water on Venus. The water vapour in its atmosphere would, if condensed, form a layer only 20 cm deep which means, in contrast to the 3-km-deep oceans that cover its sister planet Earth, that Venus is very dry indeed. It is not known with certainty whether Venus has lacked water since its formation, or if water once present has been lost during its lifetime; the question is of special interest as water is generally thought to be a necessary ingredient for the development of life. The abundance of deuterium in the atmosphere of Venus is an important clue to the planet's history, because ordinary and deuterated water escape at different rates. Using the high-resolution mode of the International Ultraviolet Explorer (IUE), we measured hydrogen Lyman- $\alpha$ -emission but found only an upper limit on deuterium Lyman- $\alpha$ -emission, from which we inferred a D/H ratio of less than  $2\text{--}5 \times 10^{-3}$ . This is smaller by a factor of 3–8 than the D/H ratio derived from measurements by the Pioneer Venus Large Probe, and may indicate either a stratification of D/H ratio with altitude or a smaller overall ratio than previously thought.

The Pioneer mass spectrometer detected a signal at mass 19 (HDO<sup>+</sup>), when the inlet became clogged by a droplet of sulphuric acid. The detection was taken<sup>1</sup> to imply a D/H ratio of  $1.6 \times 10^{-2}$ . If this modern ratio derives from an original D/H ratio similar to Earth's, that is,  $1.6 \times 10^{-4}$ , in sea water, but enriched by differential evaporation, Venus would have had enough water to form an ocean 20 m deep, although this is an extreme lower limit, because some deuterium would undoubtedly have escaped too.

The presence of HDO in the atmosphere of Venus will produce some D atoms by photodissociation and some consequent D Lyman- $\alpha$ -emission in the planet's ultraviolet airglow. In the upper atmosphere, the Lyman  $\alpha$  transition of H and D atoms can be excited by resonance scattering of solar photons, which can be observed by remote sensing from outside. The emission lines are separated by 0.33 Å (H emission is at 1,215.66 Å, and D at 1,215.33 Å), which is much more than the thermal width ( $\sim 10^{-2}$  Å) but less than the solar linewidth, so that both lines can be excited to an approximately equal extent.

The D Lyman- $\alpha$ -emission has been measured previously<sup>2</sup> in the upper atmosphere of the Earth with a dedicated Ly $\alpha$  spectrometer on board Spacelab 1, and was found to have an intensity of 300 rayleigh along a tangential line of sight at an altitude of 110 km, just above the O<sub>2</sub> absorption level. The corresponding D/H ratio was found to be  $\sim 3 \times 10^{-4}$ , indicating a twofold enrichment in D relative to sea water which results from the smaller exospheric escape for D atoms than for H atoms.

The International Ultraviolet Explorer (IUE), launched in 1978, has in principle the spectral resolution required to separate both D and H Ly $\alpha$  lines, and it was therefore proposed that it be used to detect deuterium in the upper atmosphere of Venus at the  $\sim 1\%$  level for D/H ratio following the Pioneer mass spectrometer measurement of HDO in the lower atmosphere.

A series of high-dispersion SWP (short-wavelength primary camera) spectra of the Venus dayside disk has been obtained with IUE, both in the course of this programme and in others. Measurements of the IUE echelle-grating scattered-light profile have shown that scattered H Ly emission 0.33 Å from the line centre—that is, where D Ly $\alpha$  emission should occur—is well below the level of  $10^{-2}$  expected for such emission<sup>3</sup>, so that the

detection of D Ly $\alpha$  becomes a problem of signal-to-noise ratio. In principle, the small aperture of IUE (circular, 3.2") would give the best separation of D Ly $\alpha$  and H Ly $\alpha$  spectral lines. However, the large aperture (23 × 10") has a throughput on an extended source that is greater than that of the small aperture by a factor 30, and it was found that large-aperture SWP spectra of the longest duration (that is, with the H Ly $\alpha$  emission feature saturated) provided the best measurement of D Ly $\alpha$ , despite the slight overlap of the D and H features, because of the extended size of the aperture. D emission should be apparent as an asymmetric lineshape (specifically, as a short-wavelength shoulder; see Fig. 1).

Some of the archived spectra were taken with only part of the aperture imaging the disk of Venus, leading to a distorted Ly $\alpha$  lineshape. The photowrite images of all spectra were therefore examined so as to select only those images for which the aperture was filled. A customized reduction method was required to analyse these spectra, because the aperture width used to sum the emission region in the standard IUE reduction is designed to separate the orders of the echelle and is too narrow to include all of the emission entering the large aperture. The Venus spectra contain discrete Ly $\alpha$  emission with no adjacent continuum other than longer-wavelength light scattered by the cross-disperser grating across the region of Ly $\alpha$ . In the customized reduction we therefore (1) summed the entire emission region of the Ly $\alpha$  lines; (2) employed a more extended region of background measurement for an accurate removal of the scattered light; (3) re-processed all images with VAX floating-point accuracy in the intensity transfer functions using the SDPS processing routines at Goddard Space Flight Center; and (4) carefully aligned all spectra in wavelength to the observed centre of the H Ly $\alpha$  line before summing. Thermal drifts of the spectrum across the detector face with time are advantageous, as the fixed noise pattern of the SEC cameras is altered when the images are realigned in wavelength and the noise level is therefore reduced in the summed spectrum.

The longest archived exposures of Venus lasted for 60 min: exposures longer than this were precluded by extreme saturation of the camera at the long-wavelength end of the spectrum. Six spectra ranging in duration from 30 to 60 min were summed as described and the result is plotted in Fig. 1. These spectra were obtained near the Venus maximum elongation, on 12 and 13 April and 26 August 1980. The Ly $\alpha$  intensity, estimated from other shorter, unsaturated exposures, was found to be

FIG. 1 Hydrogen Ly $\alpha$  spectra of bright-disk emission from Venus, obtained with the IUE large aperture and summing the six best images (solid line). The line intensity corresponds to  $21 \times 10^3$  rayleigh; the long-dashed line shows the line centre. The short-dashed line shows the profile calculated for deuterium Ly $\alpha$  emission of  $2.5 \times 10^3$  rayleigh (corresponding to a D/H ratio of  $1.6 \times 10^{-2}$ ). On the basis of the IUE observations, we can rule out such emission down to a factor of  $\sim 8$  times less than this. The numbers refer to spectra reference numbers and exposure times. a.u. denotes  $10^5$  IUE flux units.

$(21 \pm 5) \times 10^3$  rayleigh, which is consistent with the Pioneer Venus Orbiter ultraviolet spectrometer (PVO UVS) observations<sup>4,5</sup>. Although there is some saturation for the images summed in Fig. 1, the IUE procedure is able to account for this moderate saturation because intensity for the average spectrum is the same as that found for unsaturated exposures. The dashed line in Fig. 1 shows D Ly $\alpha$  emission of  $2.5 \times 10^3$  rayleigh modelled by scaling down the observed spectrum by a factor of 8 and displacing it by 0.33 Å. As such a shoulder does not appear in the observed spectrum, there seems to be no significant D Ly $\alpha$  emission; an examination of the noise level in this region allows us to place an upper limit ( $2\sigma$ ) of 300 rayleigh for such an emission. Although this implies an upper limit of 1.5% on the ratio of intensities, we shall see below that it implies a substantially lower D/H density ratio.

In the upper atmosphere of Venus, D and H atoms are excited by the solar Lyman  $\alpha$  line at about the same rate. However, CO<sub>2</sub> absorbs Lyman  $\alpha$  at an altitude of 110 km, and only those atoms above this level contribute to the emerging intensity. The IUE upper limit ( $2\sigma$ ) of  $I_D = 300$  rayleigh implies an upper limit for the vertical column density,  $N_D$ , of D atoms above 110 km of  $N_D = I_D \times 10^6 / g_d$ , where  $g_d$  is the excitation rate of D atoms. The ratio  $g_d/g_h$  (with  $g_h$  defined in similar fashion for H atoms) can be estimated from the relative flux intensities at the solar line centre,  $F_s$  (H excitation), and at D resonance (displaced from line centre by 0.33 Å); these measurements have been made by OSO-5 (ref. 6) (Orbiting Solar Observatory), and indicate a ratio of 0.8. The value of  $g_h$  may be found from  $g_h = 0.544 \times 10^{-14} F_s s^{-1}$ , with  $F_s = 8 \times 10^{11}$  photon  $cm^{-2} s^{-1} \text{Å}^{-1}$  at Venus (ref. 4). Variations in  $F_s$  over the 2-year period of IUE observations were smaller than  $\pm 10\%$  (ref. 5), this being confirmed by monitoring of the total solar Ly $\alpha$  flux from Earth's orbit by SME. Thus,  $g_h = 4.35 \times 10^{-3} s^{-1}$ , so that  $g_d = 3.5 \times 10^{-3} s^{-1}$  and, for  $I_D = 300$  rayleigh, we obtain  $N_D = 8.6 \times 10^{10}$  atom  $cm^{-2}$ . The photometric uncertainty of IUE at the Ly $\alpha$  wavelength is estimated as  $< 25\%$ ; indeed, the H Ly $\alpha$  intensity of  $21 \times 10^3$  rayleigh measured by IUE agrees well with the nadir, subsolar value of  $20 \times 10^3$  rayleigh measured by PVO UVS at the same time<sup>4,5</sup>.

The ratio  $I_D/I_H$  from the disk of Venus is different from the D/H density ratio in the lower atmosphere, mainly because the atmosphere above 110 km is optically thin at Ly $\alpha$  for D atoms but is moderately thick for H atoms, so that here  $I_D/I_H$  is larger than the ratio of column densities  $N_D/N_H$ . Because of the nonlinear dependence of  $I_H$  on  $N_H$ , one cannot derive  $N_H$  directly from these IUE observations. Thus to estimate  $N_H$  we use instead the Pioneer observations analysed by Paxton *et al.*<sup>4,5</sup>; these were dayside observations, made not far from the subsolar point, and therefore are pertinent to the present IUE observations.

The PVO UVS was better situated than IUE to determine an absolute value of the H density in the Venus atmosphere, because the Pioneer measurements were performed both from outside and from inside the H atmosphere, and also because the spinning geometry of PVO UVS permits measurement of bright disk intensities as well as limb profiles. The H medium is optically moderately thick so that the shape of the Ly $\alpha$  variation over one spacecraft spin depends upon the absolute H concentration everywhere between 110 km and the outside exosphere. The H density vertical distribution can therefore be determined without knowledge of either the Ly $\alpha$  centre solar flux or the UVS calibration<sup>4</sup>, by comparing radiative transfer predictions, made on the basis of a wide range of models of H density distribution, with the observations.

Paxton *et al.*<sup>5</sup> use two parameters to describe the H vertical profile: the exobase density  $n_e$  at 200 km, and the escape flux  $\phi_e$  (also at 200 km), which, for a given  $n_e$ , influences the density at the homopause level. The PVO UVS results indicate that, over the two-year period of observations (May 1979 to May 1981), the H profile near the subsolar point is remarkably con-

stant and can be described by  $n_e = (6 \pm 1.5) \times 10^4 \text{ cm}^{-3}$  and  $\phi_e = 7.5 \pm 1.5 \times 10^7 \text{ cm}^{-2} s^{-1}$ . The corresponding column density  $N_H$  above 110 km was determined to be  $(2.4 \pm 0.8) \times 10^{13} \text{ cm}^{-2}$  (ref. 5).

Combining the various uncertainties quadratically gives an upper limit ( $2\sigma$ ) to the ratio  $N_D/N_H$  of  $(3.6 \pm 1.5) \times 10^{-3}$ . The ratio of densities  $n_D/n_H$  at some reference level (say, 100 km) will be slightly different from the value of  $N_D/N_H$ , because the D and H vertical profiles are not identical. Integrating the equation of diffusion<sup>7</sup> for D atoms using the VIRA atmospheric profile<sup>8</sup> we obtain the relation  $n_D/n_H(100 \text{ km}) = \alpha (N_D/N_H)$ . If the escape flux of D atoms is zero then  $\alpha = 0.55$ ; if it is equal to the H escape flux (relative to the exobase density at 200 km) then  $\alpha \approx 1$ , and if it is 0.32 to make a rough allowance for the mass fractionation effect, then  $\alpha \approx 0.97$ .

Therefore, regardless of the value assumed for the D escape rate,  $N_D/N_H$  above 110 km is not very much different from the D/H ratio below the homopause. This is to be expected, as the homopause occurs at around 130 km well above the penetration level of Ly $\alpha$  in CO<sub>2</sub>. The upper limit of D/H at 100 km of  $\sim (3.6 \pm 1.5) \times 10^{-3}$  is lower by a factor of 4.4 than the value previously reported for the lower atmosphere<sup>1</sup>, and in fact is probably closer to  $2 \times 10^{-3}$  if present-day deuterium escape is negligible, which is entirely possible.

This low value can be compared with another set of measurements made by the Pioneer Venus Orbiter ion-mass spectrometer. Ions of mass 2 were originally identified as H<sub>2</sub><sup>+</sup> ions,<sup>9</sup> but were later assigned to D<sup>+</sup> (refs 10, 11). A detailed ionospheric model<sup>12</sup> of the pre-dawn bulge ionosphere supported this assignment to D<sup>+</sup> but showed that it required D/H neutral-atom ratios at the homopause of 1.4 and 2.5% respectively for the two orbits during which measurements were made. Clearly, the non-detection of D Ly $\alpha$  emission in the IUE data argues against such a quantity of deuterium at the homopause, suggesting that the mass-2 ions may indeed have been H<sub>2</sub><sup>+</sup> ions. To obtain an H<sub>2</sub><sup>+</sup> signal of the magnitude observed would require an H<sub>2</sub> abundance of 10 p.p.m. on Venus<sup>13</sup>, which is consistent with previous gas-chromatograph data from Venera 13-14 (ref. 14).

Despite the apparently small content of deuterium in the upper atmosphere of Venus, it is possible that more substantial amounts exist in the lower atmosphere—as suggested by the identification of a mass-19 signal, measured by the Neutral Mass Spectrometer, with HDO<sup>+</sup>—as a result of some atmospheric fractionation process. On the other hand, Spacelab-1 results have shown clearly that such processes do not operate on the Earth, and given that the aeronomy of H<sub>2</sub>O, H<sub>2</sub> and H does not seem to differ greatly for the two planets, they would not be expected to occur on Venus either. It seems possible, therefore, that the D/H ratio measured in the upper atmosphere of Venus does indeed represent the bulk atmospheric ratio. The Hubble Space Telescope will provide the means to test these results, as its High Resolution Spectrometer will be capable of resolving a D/H ratio of  $1.6 \times 10^{-4}$  (the value on the Earth) on Venus. □

# Tripolar vortices in a rotating fluid

G. J. F. van Heijst & R. C. Kloosterziel

Institute of Meteorology and Oceanography, University of Utrecht, Princetonplein, 5, 3584 CC Utrecht, The Netherlands

THE emergence of coherent flow structures is a well-known feature of quasi-geostrophic or two-dimensional turbulence, and because of their relevance to large-scale geophysical flows the dynamics of these structures have been studied increasingly over the past decade<sup>1-5</sup>. The most common coherent structures are the axisymmetric (monopolar) vortex, with circular streamlines, and the vortex dipole, both of which have been found to arise in a variety of situations under different (sometimes nondescript) forcing conditions. The emergence of vortex dipoles, for example, has been observed in turbulence in soap films<sup>3</sup>, in electrically forced magnetohydrodynamic flows<sup>5</sup> and in collapsing turbulence in a continuously stratified fluid<sup>6</sup>. There is growing evidence<sup>4,7-9</sup> that, in addition to the monopolar and dipolar vortices, a tripolar coherent flow structure exists. Here we describe a laboratory experiment in which a tripolar structure is found to emerge from an unstable cyclonic vortex in a homogeneous rotating fluid. The tripole seems to be a very stable structure, even persisting in a highly sheared fluid environment, and might therefore be found in natural geophysical flows.

Our experiment is part of a larger study of the dynamics of barotropic vortices in a rotating fluid<sup>10</sup>. The laboratory set-up (Fig. 1) consists of a cylindrical perspex tank (92.5 cm in diameter and 30 cm deep) mounted concentrically on a turntable, whose angular speed is continuously adjustable from 0 to 10 r.p.m. The tank is filled with a homogeneous fluid, and after the table has been set in steady motion, the fluid is spun-up to solid-body rotation. For these experiments the spin-up time-scale is typically 40 times the rotation period of the turntable, and the Ekman number based on the water depth is small, typically  $\sim 10^{-5}$ . Both cyclonic and anticyclonic vortices were created by briefly stirring the fluid confined in a bottomless cylinder placed at the centre of the tank. After allowing the stirring-induced flow to become a purely azimuthal flow, the inner cylinder is withdrawn vertically, releasing the vortex into the solidly rotating ambient fluid. In most experiments the Rossby number associated with the initial vortex flow—based on the vortex diameter and the maximum velocity—was large, that is, of order unity. The resulting motions were recorded photographically by a remote-controlled co-rotating camera mounted above the free surface. The flow of the initially confined fluid was traced by the addition of dye, and streak photography of small tracer particles floating on the free surface provided quantitative information on the total velocity field. Because of the two-dimensionality of the flow, the motion at the free surface, as measured from the streak lengths, is representative of the flow at lower levels.

The evolution of a cyclonic stirring-induced barotropic vortex is illustrated by the sequence of photographs shown in Fig. 2. Immediately after releasing the vortex by lifting the inner cylinder, turbulent mixing is observed in the highly sheared region at the circumference of the vortex (Fig. 2a). Within a few rotation periods, however, the flow settles in an approximately circular vortex with a smoother edge. A slightly non-axisymmetric internal structure becomes established in the dyed fluid (Fig. 2b, c), and eventually the vortex exhibits a tripolar structure, with cyclonic motion in the core and anticyclonic motion concentrated in the two satellite vortices (Fig. 2d, e, f). The tripole structure rotates in a solid-body-like manner around its centre, in a cyclonic direction relative to the rotating frame, as can be seen in the successive photographs. The motion in the interior of the tripole decays slowly, as does the overall rotation speed.

This decay is caused partly by bottom friction and partly by lateral entrainment of initially quiescent ambient fluid into the satellite vortices (visible in Fig. 2d and f). Initially (that is, just after release of the cyclonic stirring-induced vortex, Fig. 2a) anticyclonic vorticity is confined to a narrow region around the core of the cyclonic vortex. The presence of this vorticity can be inferred from the shearing of the dye filaments that get wrapped around the central structure (Fig. 2b). The anticyclonic vorticity gradually becomes concentrated in the two anticyclonic satellite vortices, an effect associated with the growth of a perturbation of azimuthal wavenumber  $m = 2$ . In many stability studies (for example, refs 11 and 12) this is found to be the fastest-growing mode for unstable circularly symmetric vorticity distributions.

In some additional experiments barotropic vortices were generated in a different way, by taking the fluid level inside the inner cylinder (Fig. 1) lower than that outside. When the cylinder is lifted, gravitational collapse results in an axisymmetric swirling motion, as would be expected from conservation of angular momentum. Although the flow immediately after the collapse is very turbulent, the motion becomes purely azimuthal typically within two rotation periods. These experiments<sup>10</sup> revealed that the vortices remain axisymmetric for relatively large values of  $\bar{H}$  and/or  $\Delta H/\bar{H}$  ( $\bar{H}$  being the mean water depth and  $\Delta H$  the difference in level), whereas a gradual transition towards a tripole structure was observed for relatively small values of both  $\bar{H}$  and  $\Delta H/\bar{H}$ . For these collapse-induced cyclonic vortices the timescale associated with the tripole formation is considerably longer than for those created by the stirring technique. This is probably a consequence of the different vorticity distributions of each type of vortex: the ring of anticyclonic vorticity encompassing the cyclonic-vorticity core is much wider for the collapse-induced vortices than for the vortices induced by stirring.

Quantitative measurements of the velocity field associated with the tripolar vortex were obtained by streak photography of tracer particles floating on the free surface; a typical example is shown in Fig. 3. Such measurements allow calculation of the spatial distribution of the vorticity  $\omega$  and the streamfunction  $\Psi$ ; the relationship between these quantities—when measured in a reference frame co-moving with the tripole—provides important information about the tripole dynamics. Although in many theoretical studies<sup>13-16</sup> of (monopolar and dipolar) coherent flow structures a linear relationship between  $\omega$  and  $\Psi$  is assumed, laboratory experiments<sup>5</sup> on magnetohydrodynamic vortex dipoles indicate the existence of a nonlinear relationship. Our preliminary laboratory measurements<sup>8</sup> of the digitized velocity field of tripole structures also suggest nonlinearity in the  $(\omega, \Psi)$  relationship; further details will be published elsewhere. The information provided by digitized streak photographs should be essential for a theoretical description of tripoles.

Although in a 'real' tripole the vorticity is distributed continuously over a compact region consisting of three aligned

FIG. 1 A schematic drawing of the laboratory set-up used to produce barotropic vortices in a rotating fluid.

patches (the two satellites and the central region, containing anticyclonic and cyclonic vorticity respectively), we can model a tripole crudely in terms of three equidistantly aligned point vortices with circulations of  $-1$ ,  $2$  and  $-1$ , respectively. Such an idealized configuration of vortices exhibits a steady cyclonic rotation around the central vortex, as observed for the laboratory tripoles. The streamfunction of the flow associated with a rotating point-vortex tripole relative to the rotating frame has been calculated<sup>8</sup>, and the corresponding pattern of streamlines (Fig.

4) shows good agreement with the dye patterns observed in the laboratory (Fig. 2*d* to *f*). But because no information about, say, the relation of the circulation of the laboratory tripole to its overall rotation rate is available yet, the quantitative value of such a point-vortex model is not clear at present.

Motivated by their interaction properties, it has been speculated<sup>17,18</sup> that isolated vortices, that is, monopolar and dipolar structures, are the 'particles' of geophysical fluid dynamics, in the sense that, although interacting, they are able to maintain

FIG. 2 A sequence of plan-view photographs illustrating the emergence of a tripolar flow structure from a cyclonic barotropic stirring-induced vortex. The photographs were taken at times of *a*,  $1.2 T$ , *b*,  $2.4 T$ , *c*,  $7.1 T$ , *d*,  $8.9 T$ ,

*e*,  $10.7 T$  and *f*,  $23.8 T$  after releasing the vortex, with  $T=8.4$  s, the rotation period of the turntable. The mean water depth,  $H$ , was  $14.5$  cm, and the initial vortex diameter,  $2R_0$ , was  $11.0$  cm.

FIG. 3 A typical streak-line photograph of the relative flow field associated with a slowly rotating tripolar vortex.

FIG. 4 Theoretical streamline pattern of a rotating tripolar vortex modelled<sup>8</sup> as three equidistantly aligned point vortices with circulations  $-1$ ,  $2$  and  $-1$ .

their structural identity much better than can dispersing waves. Monopoles and dipoles can be considered as basic flow structures in two-dimensional flows; the former are stationary features containing net angular momentum, whereas dipoles are steadily translating vortex structures that contain net linear momentum. The tripolar vortex, as found in these laboratory experiments and also in numerical simulations of two-dimensional turbulence<sup>4</sup>, appears to be an equally basic flow structure, characterized by a net angular momentum and a steady rotation of the structure as a whole. Its observed persistence in sheared fluid environments suggests that the tripole may be a robust and stable vortex structure. Tripoles have not yet been observed in large-scale geophysical flows, but in view of this apparent stability it is not unlikely that oceanic examples will be found in the near future. □

## Compositional convection in viscous melts

Stephen Tait & Claude Jaupart

Laboratoire de Dynamique des Systèmes Géologiques,  
Université Paris 7 et Institut de Physique du Globe,  
4 place Jussieu, 75252 Paris Cedex 05, France

**DURING** solidification of multi-component melts, gradients in temperature and composition develop on different scales because of the large difference between their respective molecular diffusivities. Two consequences are the development of double-diffusive convection<sup>1</sup> and the creation of mushy zones in which solid and liquid intimately coexist with a complex small-scale geometry<sup>2,3</sup>. Theoretical analysis requires simplifying assumptions that must be verified by laboratory experiments. Hitherto, experiments have been carried out with aqueous solutions which do not accurately represent the dynamics of melts with high Prandtl numbers, such as magmas. Here we describe the characteristics of compositional convection using a new experimental technique which allows the viscosity of the solution to be varied independently of chemical composition and liquidus temperature. A super-eutectic melt was cooled from below, causing the growth of a horizontal layer of crystals. Convective instability occurred when the local solutal Rayleigh number of the compositional boundary layer ahead of the advancing crystallization front attained a value of  $\sim 3$  on average. We observed a novel regime of convection in which the thermal boundary layer above the crystallization front was essentially unmodified by the motion of the plumes. The plumes carried a small heat flux and did not mix the fluid to a uniform temperature.

We have carried out experiments with aqueous solutions of ammonium chloride ( $\text{NH}_4\text{Cl}$ ) plus small amounts of

hydroxyethylcellulose compound. These low concentrations ( $< 2 \text{ wt}\%$ ) of the latter do not affect the phase diagram but nevertheless allow the solution viscosity to be varied by several orders of magnitude (Fig. 1). The solution was placed in the experimental tank and maintained at a uniform temperature above the liquidus. The base plate of the tank was connected to a pre-cooled bath at time  $t=0$ , and reached a constant temperature (below the liquidus) after a short transient. Temperatures in the fluid were measured with a vertical array of thermocouples. A few minutes after cooling began, small crystals of  $\text{NH}_4\text{Cl}$  were observed, distributed randomly at many places across the base. Growth continued by the lateral expansion of crystal patches and new nucleation until a mushy layer with a horizontal upper surface became established. Figure 2 shows the thickness of the layer as a function of time.

Our solutions contained concentrations of  $\text{NH}_4\text{Cl}$  greater than that of the eutectic point and hence fractional crystallization produced a boundary layer of light residual liquid. Compositional convection was eventually observed in the form of a field of plumes rising from the crystallizing region (Fig. 3a). The plumes consisted of cylindrical conduits and rounded caps, similar to 'diapir' plumes<sup>4</sup>. Plume cap diameters were in the range 0.3–1.0 cm, that is, substantially larger than the crystal size ( $< 0.1 \text{ cm}$ ), and increased with solution viscosity. An intriguing feature of previous experiments with ammonium chloride solutions is the formation of so-called 'chimneys'<sup>5</sup>. These are vertical channels in the mush through which strong upward flow of residual melt occurs, fed by lateral flow through the porous crystal network. Chimney formation was not observed in our experiments—we always observed the continuous generation of new starting plumes across the whole area of the tank. This is more consistent with the instability of a boundary layer at the top of the mush, analogous to the intermittent release of thermals from a diffusive boundary layer in high-Rayleigh-number thermal convection<sup>6</sup>. It may be that at higher solution viscosities chimneys develop only at times longer than the total duration of our experiments or that lateral flow in the mush is suppressed. Increasing the cooling rate at fixed viscosity resulted in a systematic increase of the critical time for the onset of convection, in agreement with previous qualitative observations<sup>5,7</sup>. Furthermore, we have observed how the critical time varies with solution viscosity (Fig. 3b).

Theory shows that convective instability of a chemical boundary layer above a flat crystal face advancing at constant velocity<sup>8,9</sup> occurs when a local Rayleigh number, defined using the boundary layer thickness ( $d$ ) as a length scale, exceeds a critical

FIG. 1 The viscosity, determined with a falling-ball viscosimeter, of 28 wt%  $\text{NH}_4\text{Cl}$  solution as a function of the concentration of cellulose additive. The approximate initial temperature of the solution was 35 °C (lower curve), and the typical temperature measured at the crystallization front was 22 °C (upper curve). Viscosities from the latter curve were used in calculations on the instability of the compositional boundary layer.

value  $Ra_c$  given by

$$\frac{g\Delta\rho_c}{D\mu}d^3 = Ra_c \quad (1)$$

where  $\Delta\rho_c$  is the compositional density difference across the boundary layer,  $g$  is the acceleration due to gravity,  $D$  is the diffusivity of the chemical species involved and  $\mu$  is the solution viscosity. In this analysis,  $d$  is given by  $D/V$ , where  $V$  is the fixed rate of advance of the crystal face.

In our experiments, constitutional supercooling occurs and, instead of a flat crystal-liquid interface, a mush forms<sup>3,10</sup>. Until the onset of compositional convection, theory predicts that temperature and composition evolve by diffusion in a regime for which the interface advances as  $2\lambda\sqrt{Dt}$ . The constant  $\lambda$  depends on the liquidus slope, the latent heat, the thermal and chemical diffusivities, and the cooling conditions<sup>2,3</sup>. In this theory, crystallization starts instantaneously at time  $t=0$ , whereas in our experiments some time is required for nucleation and the establishment of a horizontal crystal layer (Fig. 2). Some non-zero value of initial time must be adopted in order to fit a  $\sqrt{t}$  law, and times rather longer than the duration of our experiments are required to accurately verify this law. Depending on the initial temperature contrast, we obtain values of  $\lambda$  ranging from 3 to 6, which are close to those found using the theoretical framework of Worster<sup>3</sup>.

The compositional profile in the boundary layer above the mush is<sup>3</sup>:

$$C(z, t) = \Delta C \frac{\text{erfc}(z/2\sqrt{Dt})}{\text{erfc}(\lambda)} + C_i \quad (2)$$

where  $C_i$  is the initial liquid composition,  $\Delta C$  is the compositional difference across the boundary layer and  $\text{erfc}$  is the complementary error function<sup>11</sup>. Given the interface temperature and the assumption of local thermodynamic equilibrium,  $\Delta C$  was estimated for this set of experiments to be  $\sim 0.1$  wt%  $\text{NH}_4\text{Cl}$ . A rough check of this estimate was made by measuring the contrast in electrical conductivity of the solution across the boundary layer. The boundary layer thickness is defined as

$$d = \frac{\Delta C}{\left(\frac{\partial C}{\partial z}\right)} = \sqrt{\pi Dt} \exp(\lambda^2) \text{erfc}(\lambda) \quad (3)$$

which is of the form  $d = \alpha(Dt)^{1/2}$ . As  $\lambda \rightarrow \infty$ , equation (3) reduces to  $d = D/V$ , where the instantaneous velocity  $V = \lambda(D/t)^{1/2}$ . For  $\lambda > 3$ , as in our experiments, the difference between these expressions is less than 10%. Using the length scale  $D/V$  in equation (1) yields an expression for the critical time for the onset of convection,  $t_c$ :

$$t_c = \left( \frac{\lambda^3 Ra_c \mu}{g \Delta\rho_c \sqrt{D}} \right)^{2/3} \quad (4)$$

Our data support this viscosity scaling (Fig. 3b), which suggests that the essential physics of the situation is the same as for the case of a flat crystal face. Using  $D = 2.3 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$  (ref. 12) and  $\Delta\rho_c = 1 \text{ kg m}^{-3}$ ,  $Ra_c$  lies between 1 and 8, with an average value of 3, which is at the lower end of the range of theoretical results for a flat crystal face<sup>9</sup>. This suggests that fluid from deep within the mush does not participate in the initial instability. Within this framework, plume diameter should scale with the thickness of the unstable boundary layer, which is also consistent with our data.

Thermal diffusion acts over a much greater thickness of fluid than merely the compositional boundary layer above the mush. The thermal field is such as to produce a stable density gradient but the compositional field is destabilizing. Theory predicts that until the onset of compositional convection, the temperature of

the mush-liquid interface is constant<sup>3</sup>. Figure 4 shows temperature profiles in the lower part of the tank, in two different experiments, recorded as the mush-liquid interface became level with each thermocouple in turn. The viscosities of the solution at the advancing interface were 1.4 Pa s (Fig. 4a) and 0.045 Pa s (Fig. 4b). In the first case (Fig. 4a) no convection was observed. The temperature of the mush-liquid interface is essentially constant, as expected. For long times, however, it exhibits a slight decrease, probably because our tank is of finite dimensions and hence the far-field temperature does not remain constant. In the latter case (Fig. 4b) compositional convection started after 27 min and continued throughout the experiment.

The main result is that a thick thermal boundary layer is observed despite the presence of compositional convection. The heat flux carried by the plumes is small, and manifests itself by slight quantitative differences in the evolution of the temperature profiles (Fig. 4) and the rates of advance of the mush-liquid interface in the convecting and conducting cases (Fig. 2). The plumes are thin and rise slowly, equilibrating with the surroundings by thermal diffusion over a time that is short compared with their rise time. Thus they are associated with very small temperature fluctuations ( $< 0.05^\circ\text{C}$ ), as we have verified by a series of detailed continuous temperature measurements. This can be understood by considering the ratio of the buoyancy in the compositional boundary layer to that in the thermal boundary layer ( $[\Delta\rho_c/\Delta\rho_T]\sqrt{D/\kappa}$ , where  $\kappa$  is the thermal diffusivity of the solution). If this ratio has a value  $\gg 1$ , the plumes have enough buoyancy to thoroughly mix the thermal boundary layer into the overlying fluid. A ratio  $\ll 1$  implies that the thermal stratification will be essentially undisturbed. The value of this ratio is  $\sim 0.05$  in our experiments, and is  $\sim 0.005$  for basaltic magmas. We conclude that, in this regime, the heat budget is dominated by conductive transfer.

This regime of compositional convection bears some resemblance to the 'salt-finger' regime of double-diffusive convection<sup>13</sup>. In salt-finger convection, the overall density gradient is stable and vertical motion is driven by horizontal diffusion of heat. Parcels of fluid retain their compositional difference with the surrounding fluid, but the vertical temperature gradient is unperturbed by the motion. In our experiments, the overall density gradient is unstable. Because the plumes are thin and sluggish, substantial lateral thermal diffusion occurs as they rise.

Our experiments illustrate that compositional convection involves two timescales, one characteristic of crystal growth and one characteristic of convective instability. Because the composi-

FIG. 2 The rate of growth of the crystal layer.  $\Delta T$  is the temperature difference between the base plate and the initial temperature of the solution. Dashed curves are for experiments in which  $\mu = 1.4 \text{ Pa s}$  and no convection occurred. Solid curves are for experiments in which  $\mu = 0.045 \text{ Pa s}$  and abundant convection occurred. Each pair of a dashed and a solid curve show the difference in the advance of the interface for experiments with the same thermal conditions. Differences are small, indicating that compositional convection makes a small contribution to the heat budget.

FIG. 3 *a*, Photograph showing the development of crystallization and compositional convection at the base of the tank ( $\mu = 0.045$  Pa s). *b*, Measurements of the critical time ( $t_c$ ) for the onset of convection as a function of solution viscosity.  $\Delta T$  is the temperature difference between the base plate and the initial temperature of the solution.  $t_c$  increases systematically with cooling rate. The data are also consistent with the prediction based on a local Rayleigh-number instability criterion for the boundary layer that  $t_c$  scales with solution viscosity to the power  $2/3$  (solid line). This line is drawn for  $Ra_c = 3$ .

tional boundary layer itself develops by diffusion during crystal growth, it is not possible for the latter to be much shorter than the former. Approximate equality of the two timescales corresponds to the case of aqueous solutions. The other possibility, crystal growth being more rapid than the development of convective instability, may arise naturally in, for example, igneous intrusions.

In mafic magma, growth of olivine and pyroxene releases less dense residual melt and thus, by analogy with our experiments, compositional convection can occur. At the onset of convection, the vertical flux into the crystallizing region of the compatible chemical components is increased, which should result in an increase in the modal proportions of these minerals in the crystallized product. Although large undercoolings can be attained, the propagation of the crystallization front during crystallization of magma always occurs at a rate proportional to  $\sqrt{t}$  (ref. 14). We assume that compositional convection begins when the local solutal Rayleigh number exceeds a value of 3. From equation (1), the critical value of the mush-liquid interface velocity below which convection can occur,  $V_c$ , is

$$V_c = \left( \frac{g \Delta \rho_c D^2}{\mu Ra_c} \right)^{1/3} \quad (5)$$

For an illustrative calculation for basaltic magmas, we take  $\mu = 10$  Pa s,  $D = 10^{-12}$  m<sup>2</sup> s<sup>-1</sup> (values corresponding to Mg<sup>2+</sup> and Fe<sup>2+</sup> in mafic melts<sup>15</sup>) and  $\Delta \rho_c = 10$  kg m<sup>-3</sup> (ref. 16), for which equation (5) gives  $V_c = 1.5 \times 10^{-8}$  m s<sup>-1</sup>, that is, a few tens of centimetres per year.

FIG. 4 Vertical profiles of temperature in the lower part of the tank, revealing the structure of the double-diffusive boundary layer generated by crystallization. Open circles show the initial uniform temperature of the solutions. The numbers give the time in minutes at which profiles were recorded. Dashed lines show the crystallization-front temperature, solid line segments to the right of the dashed lines show the profiles above the front, and those to the left show the profiles in the mush. In both experiments, the solution has a liquidus temperature of 24 °C and the base plate temperature was 1.5 °C. *a*,  $\mu = 1.4$  Pa s,  $\Delta T = 32.5$  °C. No convection occurred, and temperature evolved by conduction alone. *b*,  $\mu = 0.045$  Pa s,  $\Delta T = 32.5$  °C. Despite abundant compositional convection, there is a thick thermal boundary layer above the front—see discussion in text.

A question of practical importance to petrologists is: what thickness of rock will have crystallized by the time compositional convection starts? The crystallization front  $X(t)$  moves according to  $X = 2\lambda^* \sqrt{\kappa t}$  (ref. 14) and thus the front velocity is  $V = \lambda^* \sqrt{\kappa/t}$ . Hence

$$X(t) = 2\lambda^* \kappa / V \quad (6)$$

Using the above value of critical velocity and taking  $\kappa = 7 \times 10^{-7}$  m<sup>2</sup> s<sup>-1</sup> and  $\lambda^* = 1$  (ref. 14), we find that  $\sim 90$  m of rock would crystallize before the onset of convection. Clearly there is a range in the values of the governing parameters for natural magmas, and here we intend to obtain only an order-of-magnitude estimate.

In mafic sills, a layer with increased modal olivine content is commonly observed at a certain distance from the lower contact. The height above the lower contact of olivine concentrations for several sills of different overall thicknesses and related to different magmatic episodes ranges from 10 to 20 m (refs 17–20). In large mafic intrusions, there is typically a basal sequence overlain by thick olivine cumulates. In the Stillwater Complex, North America<sup>21</sup>, the Muskox Intrusion, Canada<sup>22</sup> and the Great 'Dyke', Zimbabwe<sup>23</sup>, these basal sequences are observed to be about 100 m thick. The above thicknesses are all of roughly the same order of magnitude, suggesting that the appearance of mineralogical layering results from local phenomena. We propose that this may be due to the onset of compositional convection, because the thicknesses are broadly similar to the result obtained above from equation (6). This hypothesis can be verified by further petrological studies.  $\square$

## Contamination of Indian Ocean asthenosphere by the Kerguelen–Heard mantle plume

§ Department of Geological Sciences, University of Durham, Science Laboratories, South Road, Durham DH1 3LE, UK

THE mid-ocean-ridge basalts (MORBs) from the Indian Ocean are isotopically distinctive. They have higher  $^{87}\text{Sr}/^{86}\text{Sr}$ ,  $^{208}\text{Pb}/^{206}\text{Pb}$  and  $^{207}\text{Pb}/^{206}\text{Pb}$  ratios than their Pacific and Atlantic counterparts<sup>1,2</sup> (see Fig. 1), suggesting that the upper mantle beneath the Indian Ocean has remained a partially isolated system<sup>2</sup>. The Australian–Antarctic discordance, a bathymetrically depressed segment of the South-East Indian Ridge, may represent a fundamental boundary between the Indian and Pacific mantle domains<sup>3</sup>. What processes are responsible for such domains? We argue here that the Kerguelen–Heard plume, which is producing Dupal-type basalts on Kerguelen and Heard Islands in the southern Indian Ocean, has contaminated large volumes of the Indian Ocean asthenosphere. This has produced the distinctive composition of Indian Ocean MORBs.

Figure 2 illustrates the tectonic evolution of the southern Indian Ocean, and the development of tectono-magmatic features that may be attributable to the Kerguelen–Heard plume. The diagrams suggest that the plume has been involved in the development of several major features of the Indian Ocean lithosphere, and indicate that it has been active during the past 115 Myr. Lower Cretaceous continental magmatism in south-west Australia (Bunbury Basalts: 105–136 Myr BP<sup>4</sup>), north-east India (Rajmahal Traps: 108–128 Myr<sup>5</sup> and lamprophyres: 105–121 Myr<sup>6</sup>) and Antarctica (Prince Charles Mountains lamprophyres: 108–110 Myr<sup>7</sup>) imply that the plume was active during, and perhaps before, the separation of India from Antarctica–Australia at ~122 Myr<sup>8</sup>.

Major oceanic structures that can be attributed to the Kerguelen–Heard plume are the Kerguelen Plateau, emplaced during the Lower Cretaceous<sup>9</sup>, possibly at a ridge setting

analogous to that of Iceland today; and the Ninetyeast Ridge, a 5,000-km-long aseismic ridge<sup>10</sup>. Both features testify to huge volumes of magma being erupted throughout much of the Cretaceous and Tertiary. But do the chemical data for these features support the contention that they were all derived from the Kerguelen–Heard Plume? And do the data support the hypothesis that the same plume has contaminated large volumes of the Indian Ocean asthenosphere?

Kerguelen Island has been magmatically active for at least the past 40 Myr<sup>11</sup>. An important feature of Kerguelen Island magmatic activity is the changing isotopic and trace-element compositions with time; the younger basalts have higher  $\epsilon_{\text{Sr}}$  and lower  $\epsilon_{\text{Nd}}$  (refs 12, 13). During its early history, the island (and the hotspot) was probably adjacent to the embryonic South-East Indian Ridge. Mixing between plume mantle and either MORB asthenosphere or sub-plateau lithosphere diluted the effect of the plume<sup>12</sup>. Thus, the younger basalts may be isotopically more representative of the plume mantle, for example:  $^{87}\text{Sr}/^{86}\text{Sr} \approx 0.7051$ – $0.7059$ ;  $\epsilon_{\text{Nd}} \approx -1.7$  to  $-5.7$ ;  $^{208}\text{Pb}/^{204}\text{Pb} \approx 38.5$ . These isotope data are typical of Dupal-type ocean island basalts<sup>14</sup>.

Basalts from Kerguelen and Heard Islands form an array with approximately constant La/Th ratios (Fig. 3). The elements La, Ta and Th are highly incompatible in basaltic systems and ratios of these elements probably reflect the compositions of the mantle source; certainly, most ocean islands plot in distinct fields on this diagram<sup>15</sup>. Such systematic variations cannot be easily accommodated by fractionation during magma genesis. The Kerguelen and Heard array overlaps the field for Gough Island, an island in the South Atlantic with a strong Dupal component<sup>16</sup>, although some Heard Island samples have lower Th/Ta and La/Ta ratios.

In Pb-isotope space, two analysed tholeiites from the Ninetyeast Ridge<sup>1</sup> overlap the field of Kerguelen–Heard basalts (Fig. 1), suggesting a Dupal-like character. In terms of certain trace-element ratios (for example, Zr/Nb ratios<sup>17</sup>), the tholeiites are intermediate between Kerguelen Island plume basalts and MORBs. There is considerable scatter on the Th/Ta–La/Ta diagram, however, and many of the samples do not fall on such a mixing line (Fig. 3).

A suite of dredged tholeiites from the 77° graben<sup>9</sup>, in the southern part of the Kerguelen Plateau, has been analysed for Pb, Sr and Nd isotopes and major and trace elements. These results will be published elsewhere. The basalts are characterized by high  $^{207}\text{Pb}/^{204}\text{Pb}$  and  $^{208}\text{Pb}/^{204}\text{Pb}$  ratios, overlapping with the data from the Ninetyeast Ridge, the South-East Indian Ridge

FIG. 1  $^{208}\text{Pb}/^{204}\text{Pb}$  against  $^{206}\text{Pb}/^{204}\text{Pb}$  for Indian, Atlantic and Pacific oceanic basalts. Stippled ornament represents regions of thickened oceanic lithosphere.

MORBs, and the Kerguelen Archipelago (Fig. 1)<sup>18</sup>. A striking feature of the Kerguelen Plateau data is the range of Th/Ta and La/Ta ratios of the dredged basalts (Fig. 3), perhaps indicating an extreme expression of the Dupal component observed in Kerguelen Island basalts<sup>12</sup>. The extent to which the high Th/Ta ratios observed in the plateau basalts are representative of the plateau as a whole must await further data from basalts recovered during Leg 120 of the Ocean Drilling Program. We note here that high Th/Ta ratios are found in some continental flood basalts<sup>19</sup> and lamprophyres<sup>20</sup> (Fig. 3), and they are probably a feature of the continental lithosphere (crust or sub-continental mantle). The high Th/Ta ratios found in four analysed Kerguelen Plateau basalts cannot be taken to indicate that the plateau is underlain by subcontinental lithosphere. However, one interpretation is that the sub-Gondwana lithosphere, with high Th/Ta ratios, was activated and stripped by the Kerguelen-Hearde plume and incorporated in the sub-Gondwana asthenosphere (Fig. 4), and then melted out during the formation of the Kerguelen Plateau lithosphere. Alteration of the basalts to produce high Th/Ta and La/Ta ratios cannot be completely excluded but we note that all three elements have low mobility during the low-temperature alteration which has affected these samples.

The possibility arises that the long-lived, vigorous Dupal Kerguelen-Hearde plume is responsible for the Dupal-like character of modern Indian Ocean MORBs, through pervasive contamination of the sub-oceanic asthenosphere. Hamelin *et al.*<sup>2</sup> have suggested that mixing between MORB asthenosphere and plume mantle is responsible for generating the distinctive Indian MORB isotopic arrays. To fit the data, at least two stages of mixing are required: (1) an earlier contaminant (the Kerguelen-Hearde plume in this paper) which was responsible for the broad elevation in  $^{208}\text{Pb}/^{206}\text{Pb}$  (and  $^{87}\text{Sr}/^{86}\text{Sr}$ ) ratios, and which affected large volumes of the Indian Ocean asthenosphere; and (2) subsequent mixing between this contaminated asthenosphere and other high- $^{206}\text{Pb}/^{204}\text{Pb}$  mantle plumes in the central Indian Ocean (for example, St Paul and Amsterdam islands). This second event appears to be responsible for the spread to high  $^{206}\text{Pb}/^{204}\text{Pb}$  values on Pb-Pb isotope plots (Fig. 1). The La/Ta-Th/Ta data are broadly consistent with mixing between depleted MORB mantle (DMM), with a high

La/Ta ratio<sup>15</sup>, and the plume mantle. (Unfortunately, no suitable trace-element data are available for basalts from St Paul and Amsterdam islands.) However, none of the analysed South-East Indian Ridge basalts has high Th/Ta ratios. This suggests that mixing between a DMM and a high Th/Ta (lithospheric?) component was not an important process in the evolution of the sub-Indian Ocean MORB asthenosphere, although Th, La and Ta data are required from other Indian Ocean ridge segments to confirm this suggestion.

Evidence for plume contamination of adjacent sub-oceanic asthenosphere is preserved elsewhere; for example, Iceland<sup>21</sup>,

FIG. 3 La/Ta against Th/Ta for Indian Ocean basalts and (inset) other oceanic and continental (Parana) regions. Data sources: Heard and Kerguelen (K) Islands, ref. 12; SEIR MORB, ref. 30; Ninetyeast Ridge (DSDP Sites 214, 216, 253 and 254) and Kerguelen Plateau (KP), this study; Indian lamprophyres, ref. 20; Pacific (P) and Atlantic (A) MORBs are extrapolated from diagrams in ref. 15 (and references therein) assuming a Ce/La ratio of 3.0 and a Nb/Ta ratio of 17.65; Mangaia (M), ref. 28; Gough (G) and St Helena (St H), ref. 16; Parana continental flood basalts, ref. 19.

Easter<sup>22</sup> and Ascension<sup>23</sup> islands. However, in these examples the extent of contamination appears to be far less widespread than in the Indian Ocean. There may be several reasons for this. First, the Indian Ocean is a relatively compact, youthful ocean, and it originated from a locus at the Kerguelen-Heard plume. Second, the plume is very distinct from MORB in having a strong Dupal character. The component is thus more easily detected in the MORBs than are the Icelandic and Ascension signatures. Third, the plume has interacted with major spreading axes throughout its history, and therefore has had access to the Indian Ocean mantle system (the other main Dupal islands, Gough and Tristan da Cunha in the South Atlantic, have had relatively localized access to the Atlantic system); and finally, the plume appears to have been active for a long period of time, and there is strong evidence (mentioned above) that it reactivated the sub-continental lithosphere above the embryonic Indian Ocean asthenosphere. The plume could therefore have been actively contaminating the asthenosphere before the break-up of Gondwana.

Identification of mantle domains associated with specific mantle plumes can only be achieved by detailed dredging of the present-day ridge system. Klein *et al.*<sup>3</sup> have recently identified a potential boundary between two oceanic mantle domains,

which may represent the eastern influence of the Kerguelen plume system. There are too few data to identify the western limit of the influence of the KHP; the basalts of the South-West Indian Ridge appear to have a Walvis Ridge component<sup>2</sup>, indicating the influence of another Southern Hemisphere Dupal domain. The unknown factor is the extent to which many of the distinctive Dupal characteristics—in plumes or MORBs—result from long-term residence beneath the stable Gondwana supercontinent.

## Genetic specialists, kin recognition and nepotism in honey-bee colonies

Robert E. Page Jr, Gene E. Robinson & M. Kim Fondrk

Department of Entomology, The Ohio State University, 1735 Neil Avenue, Columbus, Ohio 43210-1220, USA

INSECT societies have long served as useful models in the study of two often intertwined issues in evolutionary biology: the levels at which natural selection operates<sup>1</sup>, and the phenomena of competition and cooperation in animal societies<sup>2</sup>. Hamilton<sup>3–5</sup> provided a darwinian explanation for the evolution of cooperation by invoking natural selection for increased inclusive fitness, whereas Trivers and Hare<sup>6</sup> showed how asymmetrical genetic relationships among members of hymenopteran societies result in differential fitness among queens and workers and can lead to conflict over the production of males. Here we provide evidence for competition among workers of the honey bee, *Apis mellifera*, in the production of female reproductives, a consequence of the genetic structure of colonies resulting from polyandry<sup>7</sup>, genotypic biases in components of cooperative behaviour associated with division of labour<sup>8–10</sup>, and kin recognition<sup>11–13</sup>. We also propose that nepotistic behaviour by honey bees is influenced by both kin- and colony-level selection.

Honey-bee colonies normally consist of about 17 subfamilies<sup>7</sup>. Members of the same subfamily, super sisters<sup>14</sup>, share both a

queen mother and a drone father and, in the absence of inbreeding, have a coefficient of genetic relationship of 0.75 (ref. 15). Half-sisters belong to different subfamilies, share only a mother, and have a genetic relationship of 0.25. We tested the ability of workers to discriminate during the rearing of queens in colonies that were derived from instrumentally inseminated queens and composed of three biochemically-distinct subfamilies. Samples of immature (larvae and prepupae) queens and workers, and adult workers located near either immature queens or workers, were collected from experimental colonies and analysed by protein electrophoresis to determine the frequencies of individuals belonging to each of the three subfamilies (see Fig. 1 and Table 1 for details).

Any observed subfamily biases in queen production could be a consequence of intracolony kin recognition coupled with one or more of four mechanisms: (1) workers preferentially raise the most familiar larvae, that is, those belonging to the subfamily with the highest larval frequency; (2) workers prefer-

entially raise the rarest larvae; (3) the subfamily with the most adult members on queen cells dominates queen rearing and preferentially raises super sisters; and (4) biases occur in the proportional representation of subfamilies engaged in the rearing of queens (relative to larval frequencies) and individuals preferentially rear super sisters. To determine which, if any, of these mechanisms are involved, four series of Monte Carlo simulations were conducted based on the results of our allozyme analyses. Each series of simulations focused on a different 'test'-subfamily that was appropriate to each one of these four possible mechanisms.

Our results demonstrate nepotism during the rearing of queens. Individual workers were located on or off queen cells, at least in part, on the basis of genotypically determined factors. Treatment of immature queens (involving perhaps differential feeding and/or selective removal) was apparently mediated by genetic relatedness with a small but consistent rearing preference shown for more closely related larvae. Subfamilies with a bias

Total deviation = +60											

The table demonstrates nepotism in the rearing of queens by honey bees based on kin recognition and subfamily differences in the likelihood of raising queens (mechanism 4 in text). In this case the 'test'-subfamily (one per trial for each colony, three trials total) was selected because it exhibited a higher probability of being located on queen cells than other subfamilies in the colony. For the analysis, four different sets of 'test'-subfamilies were selected, each set appropriate to one of the four hypothesized mechanisms underlying biases in the rearing of queens. To test the hypothesis of mechanism 4 we determined the relative likelihood of rearing queens,  $RL_s$ , for individuals of each subfamily ( $s$ ) within a colony:  $RL_s = PA_s / PI_s$ , where  $PA_s$  is the proportion of subfamily  $s$  in sample of adults on queen cells, and  $PI_s$  is the proportion of subfamily  $s$  in sample of immature workers. The subfamily with the highest value of  $RL$  for each colony in each trial was designated the 'test'-subfamily for mechanism 4. The expected number of queens for the test-subfamily  $E(Q_i)$  was then calculated from the equation  $E(Q_i) = (I_i/N)$ , where  $I_i$  is the proportion of test-subfamily in sample of immature workers, and  $N$  is the total number of queens raised in a given trial. The difference between  $E(Q_i)$  and the observed number of queens  $O(Q_i)$  was then calculated to determine the deviation. Because conventional analyses of contingency tables were inappropriate<sup>16</sup> (workers selected queens without replacement from among a finite sample of 60 transferred larvae), we used Monte Carlo simulations to estimate the probability of getting a deviation that was as great or greater than our result. For each of the four hypothesized mechanisms, the Monte Carlo simulation randomly drew a number of immature workers equal to the actual sample from a very large (infinite) pool with appropriate test-subfamily frequencies equal to the weighted average of the immature worker and queen samples. It then drew an independent random sample of immature queens from the same pool and calculated the deviation from expected as described above. Deviations were summed for all trials of all colonies. The simulation was iterated 1,000 times and iterations in which the total deviation was as great or greater than that observed were summed. The probability of getting a result as extreme as that observed was calculated as the number of iterations with a total deviation greater than that observed divided by 1,000. The entire simulation process was repeated five times to give an estimate of the standard error of the simulation-generated probability. Observed deviations cannot be a consequence of nonrandom sperm usage by queens because  $E(Q_i)$  and  $O(Q_i)$  were both based on the same samples of immature females.

in adult representation as queen nurses, relative to the available potential queen larvae, biased the colony's output of queens in their favour.

On average, only half ( $\bar{X} = 30 \pm 11.8$  s.d.; 916 queens were raised in total) of the 60 transferred larvae were raised during each trial of each colony, thus providing ample opportunity for workers to make 'choices' with respect to which larvae become queens. Combining data from all trials of all colonies, the subfamilies whose adult members had the highest within-trial individual probability of being sampled on queen cells (mechanism 4; Fig. 1) collectively had 60 more super-sister queens raised than expected on the basis of samples of immature workers ( $P = 0.001 \pm 0.0002$  s.e.,  $n = 5$  Monte Carlo simulations; see Table 1). In contrast, members of the numerically most common subfamily, again based on samples of immature workers (mechanism 1), had 37 fewer queens raised than expected. Individuals belonging to the rare subfamily (mechanism 2) had 13 more than expected ( $P = 0.179 \pm 0.0066$ ), and those belonging

FIG. 1 Expected and observed number of queens reared for each of four mechanisms hypothesized to result (along with kin recognition) in nepotism in the rearing of queens by honey bees. The inset depicts the per cent deviation of the observed from the expected values for each mechanism. For explanation of statistical analyses see legend for Table 1.

**METHODS.** Ten colonies were established, each composed of three electrophoretically distinguishable subfamilies. The colonies' queens were daughters of three unrelated queen mothers. Drones for matings were progeny of eight additional unrelated queens. Each of the ten queen daughters was instrumentally inseminated<sup>23</sup> with semen from three unrelated drones, each one bearing a different malate dehydrogenase-1 (*Mdh*) marker allele, designated 'slow' (S), 'medium' (M) and 'fast' (F)<sup>24</sup>. Semen from each drone trio was pooled, diluted, and mixed before insemination to minimize temporal fluctuations in subfamily frequencies<sup>25,26</sup>. Four of ten inseminated queens were homozygotes at the *Mdh* locus (SS: colonies 4438, 4440, and 4456; MM: colony 4453), producing female progeny with three allozyme phenotypes that correspond to three subfamilies. Five queens (colonies 4439, 4442, 4445, 4450, and 4464) were SF heterozygotes that produced three subfamilies with five allozyme phenotypes: SS, SM, SF, MF, and FF. Larval and adult bees sampled from these colonies were grouped into three subfamilies as follows. SM and MF bees were assigned to the M subfamily because the M allele could only be paternally inherited. SF bees were assigned to the S and F subfamilies in proportion to the ratio of SS and FF phenotypes in each sample, because the maternal S and F alleles are expected to segregate in a 1:1 ratio. Subfamily membership was determined similarly for individuals from colony 4457, derived from a SM queen. The experiment took place from April to May, 1987, under conditions of seasonal production of queens associated with normal colony reproduction through fission<sup>27</sup>. At the start, nine of ten colonies (all except 4445) were raising queens naturally. Colonies occupied hives consisting of two or three chambers; the lower two were filled with combs of brood and honey, and the third with honey and empty combs. Each queen was confined to a bottom chamber of the hive with a queen excluder. For each colony, 60 newly hatched female larvae were transferred from a frame of worker comb containing up to 3,700 individual larvae into dry, artificial queen cells arranged 20 cells to a bar, three bars to a frame (female larvae located in special queen cells are fed differentially and develop into queens rather than workers<sup>28</sup>). The two frames were placed together in the centre of the upper brood chamber in each hive, with the queen cells closest to the side from which larvae were transferred. Three days later we removed the two frames, with minimal disturbance, and collected ~50 workers each from the surface of the queen cells and from the area of worker comb that originally contained the transferred larvae. These were assumed to be queen and worker 'nurses', respectively. Immatures (larvae and prepupae) were sampled six days after transfers when all investment in new queens was complete and the queen cells were capped by the workers<sup>28</sup>. In addition to collecting all queen cells, we gathered samples of about 50 immature workers that were the same age and located in the same area of the comb as were the queen larvae before they were transferred. All samples were stored at  $-70^{\circ}\text{C}$  until analysed by electrophoresis. Each colony was tested three times at 7–8-day intervals for a total of 30 trials. All queens, 34–51 immature workers, and 34–43 adult workers per sample were analysed.

to the subfamily with the highest frequency of adult workers on queen cells, regardless of numerical representation in the colony (mechanism 3), had an excess of 34 raised ( $P = 0.064 \pm 0.0034$ ). In 13 of the 18 trials that showed a positive bias in the rearing of queens, assuming mechanism 3, the numerically dominant adult subfamily was also the one whose members had the greatest bias in likelihood of being sampled as queen nurses and, therefore, were also classified as the test subfamily based on mechanism 4. In these cases, mechanisms 3 and 4 were confounding.

Genetic 'specialization' for rearing queens is suggested by the following results. In four of ten colonies, the subfamily distribution of adult workers sampled on queen cells differed significantly from the distribution of adult workers sampled on the adjacent comb containing worker larvae in at least one of three trials, even though the sampled frames were only ~2–4 cm apart ( $P < 0.05$ , colony 4440;  $P < 0.01$ , 4450;  $P < 0.01$ , 4456;  $P < 0.05$  and  $P < 0.01$ , 4464;  $G$  tests of heterogeneity<sup>16</sup>). In two colonies subfamily differences were significant for the three trials combined ( $P < 0.01$ , 4453 and  $P < 0.05$ , 4456). The number of trials that showed a significant deviation ( $P < 0.05$ ) was greater than that expected based on chance alone ( $P < 0.02$ ; binomial test, assuming 30 independent trials). These differences may be due either to paternally inherited behavioural traits that generate a bias in the representation of adult subfamily members on queen cells relative to their representation in the pool of potential queen zygotes, or, alternatively, to nonrandom sperm use by queens coupled with age differences between queen 'nurses' and worker 'nurses'. Results based on analyses of patterns of sperm use for each queen do not support the alternative explanation. The subfamily distribution in worker larvae samples fluctuated significantly among trials in only two of ten colonies ( $P < 0.01$ , 4445 and 4450), suggesting that the sperm of the three drones used for each insemination were well mixed in eight colonies.

Subfamily biases for the rearing of queens were small and consistent with previous studies. The ratio of the proportion of test-subfamily (assuming mechanism 4) adults sampled on queen cells to its proportion in the sample of worker larvae (see Table 1 legend) was  $2.3 \pm 1.90$  s.d. The mean ratio of the observed to the expected number of test-subfamily (mechanism 4) queens raised, based on the worker larval samples, was  $1.5 \pm 1.10$  s.d. Page and Erickson<sup>17</sup> reported a ratio of 1.6 in the number of queens reared when workers were given a choice of super-sister and less related ( $G = 0.25$  or  $0.31$ ) non-nestmate larvae. Visscher<sup>18</sup> found a bias of 1.5 in favour of a mixture of super- and half-sister nestmate eggs or larvae over unrelated non-nestmates. Noonan<sup>19</sup> demonstrated a bias of 1.2 in the visitation frequency of adult workers to queen cells containing super- versus half-sister larvae in colonies composed of two visually distinguishable subfamilies.

In agreement with previous studies<sup>8–10</sup>, our results suggest that the genotypes of workers affect colony organization by influencing the probability of performing behaviour associated with the division of labour. Worker genotype also results in differential social interactions, some of which may lead to intranidal conflict. Simply determining genetic relationships among colony members is not sufficient for testing kin-selection theory; the genetic relationships among interacting individuals must be considered (compare with ref. 20). Our results also demonstrate that kin selection is an important process in the evolution of social interactions involved in reproduction.

Larval kin recognition should increase the adaptive value of genotypes that result in a higher probability of the rearing of queens, driving them rapidly to fixation in populations. Perhaps this is a social analogue of meiotic drive<sup>21</sup> that distorts the proportional representation of queen genotypes (M.D. Breed, personal communication). Genetic variability and the rather modest levels of nepotism observed may be functionally linked and represent a compromise between levels of selection<sup>22</sup>. Kin selection may favour alleles that result in intracolony competition: high propensity to rear queens, better recognition, and

more discrimination. However, variation in the rearing of queens coupled with larval discrimination may reduce the reproductive output of colonies, a consequence of decreased rearing of queens due to adult-adult or adult-larva conflict, or a decrease in the ergonomic efficiency of the colony. If so, then colony-level selection may favour cooperation: a lower propensity for rearing of queens, and less discrimination. With additional genetic analyses of insect societies, the functional significance of the observed genetic variability, and the mechanisms underlying the intricate interplay of competition and cooperation may be further elucidated. □

## Root lectin as a determinant of host-plant specificity in the *Rhizobium*-legume symbiosis

Clara L. Díaz\*, Leo S. Melchers†, Paul J. J. Hooykaas†, en J. J. Lugtenberg\* & Jan W. Kijne\*

Department of Plant Molecular Biology, Leiden University, \*Nonnensteeg, 3, 2311 VJ Leiden and †Wassenaarseweg 64, 2333 AL Leiden, The Netherlands

**THE induction of nitrogen-fixing nodules in legume roots by soil bacteria from the genera *Rhizobium* and *Bradyrhizobium* is host-plant-specific. This specificity is expressed at an early stage of the infection process and results from multiple interactions between bacterial and plant products. Among these, it has been suggested that root lectin recognized by bacterial receptor molecules is an important determinant of host specificity<sup>1,2</sup>. Lectins are carbohydrate-binding proteins and it is known that legumes belonging to different cross-inoculation groups produce lectins with different sugar-binding specificities<sup>3</sup>. We have tested this suggestion by introducing the pea lectin gene into white clover roots using *Agrobacterium rhizogenes* as a vector. The 'hairy' clover roots that result can be nodulated by a *Rhizobium* strain usually specific for plants from the pea cross-inoculation group.**

*Rhizobium leguminosarum* bv. *viciae* nodulates the cross-inoculation group of pea, vetch and lentil, whereas clover is nodulated by *R. leguminosarum* bv. *trifolii*. The involvement of root lectin in determining this host-plant specificity was tested

by introducing the pea lectin gene (*psl*) into the roots of white clover and by studying the infection of transgenic clover roots by *R. leguminosarum* bv. *viciae*. Transgenic roots rather than transgenic plants were studied because of the problems of regenerating the latter.

We cloned *psl* into a binary vector<sup>4</sup> using *A. rhizogenes* LBA1334 (Ar1334) (ref. 5) to obtain transgenic clover roots. The *psl* gene encodes a glucose/mannose binding protein<sup>6,7</sup> and is expressed at low and developmentally controlled levels in pea roots during the plant's life cycle<sup>8</sup>. Pea lectin is localized at the surface of growing pea root hairs, which are the target cells for rhizobial infection<sup>9</sup>. Lectin-enhanced accumulation of infective rhizobia at pea root-hair tips correlates with increased infectivity of the rhizobial cells<sup>10</sup>.

Complete genomic *psl* (*psl* *lecA* provided by J. A. Gatehouse<sup>7</sup>) was cloned in the binary vector pBin19 (ref. 11). In addition, the full length *psl* complementary DNA<sup>12</sup> (provided by M. Stubbs) was cloned in the binary expression vector pAGS 35S HB (ref. 13) (provided by C. M. P. van Dun) between the plant viral 35S promoter and the nopaline synthase 3' end. These binary vectors are referred to as pBin19 *psl* and pAGS *cpsl*, respectively. (For details of the cloning steps see Fig. 1.)

The efficiencies of the binary vector systems were tested by determining the activity of a reporter gene product. Both vectors carry a neomycin phosphotransferase gene (NPTII, see Fig. 1) which can be expressed in transformed plant tissue. Hairy roots

*Trifolium repens* L. (white clover) seedlings were grown with their roots on filter paper in Petri dishes containing Jensen-1% agar<sup>14</sup> supplemented with 0.5 mM Ca(NO<sub>3</sub>)<sub>2</sub>. Transformation was achieved by superficially wounding the stems of 6–8-day-old seedlings 2 mm under the first pair of leaves with the tips of an electron microscope grid forceps (number 7, Dumont, Switzerland) carrying *A. rhizogenes*. Bacteria were grown on LC (ref. 24) plates containing full antibiotic concentrations (see Fig. 1 legend) for Ar1334, Ar1334 carrying pBin19 or Ar1334 harbouring pAGS *cpsl* or pBin19 *psl*. Following transformation, the main root was excised 2–3 mm under the wound and the first hairy roots emerged from the wound sites 4–5 days later in all plants. Seedlings were transferred to fresh nutrient plates 5–7 days after wounding and nodulation assays were performed as described previously<sup>14</sup>. For re-isolation of rhizobia, red nodules were surface-disinfected in 5% H<sub>2</sub>O<sub>2</sub> for 10 min, rinsed in sterilized water and crushed in 250 µl B-medium<sup>25</sup> and plated on B-medium<sup>25</sup>. Re-isolates from R/248 Rifr-induced nodules were rifampicin-resistant, in contrast to re-isolates from R/843-induced nodules. Colonies from re-isolated rhizobia were blotted to nitrocellulose sheets and allowed to react with monoclonal antibody (mAb) 3, specific for the O-antigen of R/248 (ref. 21). Only re-isolates from R/248 Rifr-induced nodules were recognized by mAb 3. Rhizobial cell envelopes were analysed by SDS-polyacrylamide gel electrophoresis as previously described<sup>26</sup>. A protein of relative molecular mass 45,000 and characteristic of R/248 Rifr (control) was present in bacteria re-isolated from R/248 Rifr-induced nodules and absent from re-isolates from R/843-induced nodules. Nodulation of *Vicia sativa* L. by R/248 Rifr-re-isolates and their failure to nodulate white clover roots confirmed that *R. leguminosarum* bv. *viciae* 248 Rifr nodulates hairy roots of white clover co-transformed with pBin19 *psl* or pAGS *cpsl*. White clover seeds of cultivar 'Dutch Clover' (6990.6300) were purchased from Kieft, Blokker, The Netherlands.

† Red nodules.

‡ Pseudonodules.

§ Red and white nodules and pseudonodules.

FIG. 1 Insertion of the pea lectin gene (*psl*) into binary vectors. To subclone the lectin cDNA as a *Hind*III fragment between the cauliflower mosaic virus (CaMV) 35S promoter and the nopaline synthase (NOS) polyadenylation signal of the binary vector pAGS HB 35S (a derivative of pAGS127) (ref. 13), *psl* cDNA (from plasmid pMS2) (ref. 12) coding for a segment of the lectin's leading signal and the complete  $\beta$ - and  $\alpha$ -chains, was first cloned into pIC-19H (ref. 7). The binary vector carrying the chimaeric pea lectin gene is pAGS *cpsl* (Fig. 1a). The complete genomic gene for *psl* (lecA) (ref. 7) was isolated as a *Hind*III–*Eco*RI restriction fragment and cloned into pBin19 (ref. 11). The resulting vector is termed pBin19 *psl* (Fig. 1b). Binary vectors were mobilized from *Escherichia coli* to *A. rhizogenes* LBA1334 (Ar1334) in a triparental mating using pRK2013 (kept in HB101 cells) as a helper plasmid<sup>24</sup>. Ar1334 is a derivative of *A. tumefaciens* strain C58C9 with a chromosomal marker for rifampicin resistance and harbours the agropine type pRI855 plasmid equipped with a spectinomycin resistance marker<sup>5</sup>. Ar1334 cells harbouring pAGS *cpsl* and Ar1334 cells carrying pBin19 *psl* were kept on LC plates<sup>24</sup> containing rifampicin (20  $\mu$ g ml<sup>-1</sup>) plus tetracycline (2  $\mu$ g ml<sup>-1</sup>), and rifampicin (20  $\mu$ g ml<sup>-1</sup>) plus kanamycin (100  $\mu$ g ml<sup>-1</sup>), respectively. To check if the binary vectors were present in Ar1334, plasmid DNA was isolated<sup>28</sup> and immediately transformed to MH1-competent cells. Plasmid preparations from *E. coli* and analysis of restriction patterns showed that both binary vectors were maintained in Ar1334 cells. Restriction enzyme digestions, agarose gel electrophoresis, dephosphorylation, annealing of restriction fragments and transformation to *E. coli* followed procedures described elsewhere<sup>29</sup>. Isolation of restriction fragments was performed with glass beads<sup>30</sup> (GeneClean, Bio 101). Restriction sites are denoted: B, *Bam*HI; Bg, *Bgl*II; E, *Eco*RI; EV, *Eco*RV; H, *Hind*III. Other abbreviations: LB, left border; RB, right border; NPTII gene, neomycin-phosphotransferase II gene; P35S, CaMV 35S promoter; Tnos, nopaline synthase terminator.

were induced on a set of clover seedlings which were grown on filter paper for 13 weeks in large Petri dishes (15 cm in diameter), filled with 100 ml plant growth medium<sup>14</sup> containing 5 mM KNO<sub>3</sub> and 1% agar (see Table 1). The dot assay for NPTII activity<sup>15</sup> was performed with extracts from randomly chosen hairy roots weighing from 50–100 mg. Hairy roots induced by Ar1334 (or adventitious roots) did not have any NPTII activity, whereas 86% (of a total of 64 samples) of hairy roots induced by Ar1334 harbouring pBin19 *psl* did have NPTII activity. Similar percentages of co-transformation (70–80%) using pBin19 contained in *A. rhizogenes* LBA9402 have been reported for several plant species<sup>16</sup>. The enzymatic assay was also positive for 42% (of a total of 66 samples) of the hairy roots induced by Ar1334 carrying pAGS *cpsl*. These results show that the binary-vector system of transformation is an efficient tool for introducing foreign genes into host plants.

To study the nodulation properties of white clover hairy roots, young hairy roots, 1–3 cm in length, were inoculated with *R. leguminosarum* bv. *trifolii* ANU843 (Rt843) (ref. 17). As with normal young white clover seedlings, nodules emerged 4–6 days

after inoculation on the roots of clover transformed with Ar1334, Ar1334 carrying pBin19 and Ar1334 harbouring pBin19 *psl* or pAGS *cpsl*. Nodules continued to be initiated along the first formed hairy roots and even on hairy roots which emerged 4–6 weeks after transformation. With few exceptions, nodules were red and the acetylene reduction assay<sup>14</sup> indicated that nodules on hairy roots could reduce atmospheric nitrogen. Nodules were distributed on all hairy roots, and plants had 12–100 nodules. Most of the nodules remained small, particularly in heavily nodulated hairy roots. Electron micrographs of these nodules<sup>18</sup> showed no differences with nodules induced by Rt843 on normal white clover roots with respect to the morphology, and the number and shape of bacteroids. These results show that white clover hairy roots behave as normal roots in nodulation, and that nodulation of white clover hairy roots by the homologous symbiont is not in any way inhibited by the presence of the binary vector T-DNA with or without the *psl* gene.

Rifampicin-resistant *R. leguminosarum* bv. *viciae* strain 2<sup>40</sup> (RI248 Rif<sup>R</sup>) (ref. 19) did not nodulate white clover hairy roots induced by Ar1334 or by Ar1334 carrying pBin19 without the

FIG. 2 Nodulation of white clover hairy roots co-transformed with the pea lectin gene by *Rhizobium leguminosarum* bv. *viciae*. Hairy roots induced by Ar1334 or by Ar1334 carrying pBin19 were not nodulated by RI248 Rif<sup>R</sup> (Fig. 2a). The host range of nodulation of white clover hairy roots, co-transformed with the genomic or copy DNA of *psl*, however, is extended to include *R. leguminosarum* bv. *viciae* 248 Rif<sup>R</sup>. Of the nodulated plants co-transformed with pBin19 *psl* or with pAGS *cpsl*, 30% had 1–4 red nodules, whereas 5–10% had 5–12 red nodules. These nodules could not be distinguished from nodules induced by Rt843 on Ar1334-induced hairy roots. Some of the nodules formed after inoculation with RI248 Rif<sup>R</sup> were red as soon as they emerged and matured within 4–8 days (b), others emerged white, grew out in 8–16 days and then turned red. The assay for acetylene reduction<sup>14</sup> was positive, indicating that red nodules induced by RI248 Rif<sup>R</sup> were able to reduce atmospheric nitrogen. All nodulated plants (Table 1) had ~1–50 white, small outgrowths, such as those indicated by arrows in c. In some cases these outgrowths developed

into white or red nodules; in most cases they did not grow further and were categorized as pseudonodules.

FIG. 3 Electron microscopy of red nodules induced by *Rhizobium leguminosarum* bv. *viciae* on white clover hairy roots co-transformed with the pea lectin gene. Adjacent red nodules on co-transformed roots were chosen for rhizobia re-isolation and identification, and processing for electron microscopy<sup>18,23</sup>. Examination of the micrographs showed that the ultrastructure of nodules induced by *Ri248* Rif<sup>R</sup> did not differ from that of nodules induced by *Rt843*. *a*, Longitudinal section of a young nodule formed on a hairy root of a clover plant co-transformed with the complete pea lectin genomic gene. The meristematic (M), infection (I) and bacteroid (B) zones are well distinguished; C is the nodule cortex. Scale bar, 1  $\mu$ m. *b*, A longitudinal section of an infection thread as observed in the infection zone. Note the continuity of the host's plasmalemma (P) delimitating the thread matrix (M) and the gradual decrease of the thread wall material (TW) towards the tip of the infection thread. Rhizobia (R) are seen being released into the host cell cytoplasm by endocytosis (arrow). V, vacuole; N, nucleus. Scale bar, 100  $\mu$ m.

*psl* gene (Fig. 2a, Table 1). Moreover, infection threads could not be observed by microscopical light-examination of methylene blue-stained hairy roots. In both cases, however, white clover hairy roots responded to inoculation with *Ri248* Rif<sup>R</sup> with marked root-hair curling, as has been previously reported for normal clover roots<sup>20</sup>. Forty to sixty days after inoculation the hairy roots of 1 in 20 plants presented one or two white outgrowths. Their examination by electron microscopy, however, failed to reveal the presence of infection threads and they were therefore categorized as pseudonodules. These results show that as with normal roots, nodulation of white clover hairy roots is host-specific. Moreover, the insertion of a functional NPTII gene into co-transformed white clover hairy roots did not affect this specificity.

The *psl* gene appeared to affect the host-range of nodulation. Hairy roots induced with *Ar1334* carrying binary vectors either with the complete genomic *psl* or cDNA construction were inoculated with *Ri248* Rif<sup>R</sup>. Nodules confined to one or two hairy roots and their lateral roots (Fig. 2b) began to emerge 20 days after inoculation (Table 1). Such a distribution of nodules is accounted for by (1) not all the roots of a transformed seedling being hairy roots, and (2) not all hairy roots containing the pea lectin gene. These two types correspond to the roots of non-transformed clover plants and to hairy roots induced by *Ar1334* by *Ar1334* containing pBin19, respectively, which are both resistant to infection by *Ri248* Rif<sup>R</sup>. Electron micrographs of red nodules (Fig. 3) showed that their structures were similar to those of nodules induced by *Ri248* Rif<sup>R</sup> on *Vicia sativa* roots and by *Rt843* on *Trifolium repens* roots. The presence of stunted nodules, or pseudonodules (Fig. 2c) however, indicated that in many cases infection was aborted. Electron micrographs of those pseudonodules revealed degenerated nodule meristems, bacteria in intercellular spaces deep in the root cortex and aborted infection threads.

Rhizobia were re-isolated from red nodules on hairy roots that had been co-transformed with the *psl* gene (Table 1). The heterologous symbiont *Ri248* Rif<sup>R</sup> was identified using five criteria: (1) the rate of growth on B-agar plates, (2) antibiotic resistance; (3) positive reaction with a monoclonal antibody specific for the O-antigen of *Ri248* (ref. 21); (4) SDS-PAGE pattern of cell envelope proteins; and (5) nodulation of *V. sativa* L. and failure to nodulate *T. repens* L<sup>5</sup>. From this identification we concluded that *Ri248* Rif<sup>R</sup> is able to induce root nodules on white clover hairy roots co-transformed with the *psl* gene. Nodulation, however, is delayed and most nodules are abnormal.

Our results show that the host range in *Rhizobium*-legume symbiosis is at least partially determined by symbiont-root-

lectin interactions. The introduction of the gene encoding the glucose-/mannose-binding pea lectin in clover roots allows infection by *R. leguminosarum* bv. *viciae* to proceed beyond root-hair curling. This indicates that root lectin contributes to a mechanism by which the plant selectively allows a homologous *Rhizobium* to penetrate root cells and induce infection threads. Our results also provide the first example of a host-specificity barrier in a plant-bacterium interaction being broken by genetic engineering of the host plant. Interaction of host lectin with the homologous symbiont might either induce increased infectivity of the rhizobia<sup>22</sup> or enable collective endocytosis of rhizobia in the root hair curl<sup>23</sup>. It is also conceivable that the introduction of *psl* to clover induces a response to *R. leguminosarum* bv. *viciae* bacteria which does not directly involve pea lectin. The fact that lectins with a sugar specificity similar to pea lectin are specifically present in plants of the pea cross-inoculation group, however, suggests that this is unlikely. □

ACKNOWLEDGMENTS. We thank John Gatehouse (University of Durham) and Marlene Stubbs (University of Toronto) for their gifts of the pea lectin genes, Cees M. P. van Dun for pAGS HB 35S and Ruud de Maagd for Mab3. We also thank Saskia Rueb, Amke Den Dulk-Ras, Pauline van Spronsen, and Teun Tak for technical assistance.

FIG. 2 Saturation isotherm of [ $^3\text{H}$ ]Ro15-1788 binding. Inset, the corresponding Scatchard plot ( $K_d = 0.97 \text{ nM}$ ,  $B_{\text{max}} = 3.2 \text{ pmol mg}^{-1} \text{ protein}$ ). In three independent transfection experiments  $K_d$  values of  $1 \pm 0.2 \text{ nM}$  and  $B_{\text{max}}$  values of  $2.7 \pm 0.7 \text{ pmol mg}^{-1} \text{ protein}$  were obtained.

**METHODS.** Human  $\alpha 1$ -,  $\beta 1$ - (ref. 11) and  $\gamma 2$ -encoding cDNAs, subcloned individually into the expression vector pCIS2 (ref. 27), were used to transform human embryonic kidney 293 cells as described previously<sup>5,28</sup>. After transfection (48 h), cells from ten plates (10 cm;  $4 \times 10^6$  cells per plate) were washed twice with phosphate-buffered saline (PBS) and scraped into PBS (10 ml). The cell pellet (500g) was homogenized in a Polytron tissue homogenizer (Brinkmann) in 10 ml of 10 mM potassium phosphate, pH 7.4, and centrifuged (50,000g, 20 min). This procedure was repeated three times and the final pellet resuspended in potassium phosphate buffer, pH 7.4, containing 100 mM KCl. For each ligand concentration, triplicate homogenates, each equivalent to  $10^6$  cells (100  $\mu\text{g}$  protein), were incubated (4  $^{\circ}\text{C}$ , 60 min) in a 1 ml reaction volume with [ $^3\text{H}$ ]Ro15-1788 (NEN, 75 Ci mmol $^{-1}$ ). Non-specific binding was determined in the presence of  $10^{-6} \text{ M}$  clonazepam and was  $<10\%$  of total binding.  $K_i$  values of clonazepam, diazepam, and DMCM (see text) were determined in similar reactions using  $10^{-10}$ – $10^{-5} \text{ M}$  unlabelled competitor compounds. Samples were vacuum-filtered on GF/C filters with a vacuum filter apparatus (Biorad) and filters were washed twice with 5 ml homogenization buffer. After drying, filter-retained radioactivity was determined by liquid scintillation counting.

domain, as well as four transmembrane segments. The greatest sequence similarity to  $\alpha$ - and  $\beta$ -subunits occurs in the region of these transmembrane segments and includes the charged amino-acid residues thought to form the channel mouth<sup>3,7</sup>. The proposed large intracellular domain displays the highest sequence divergence among the subunits. In the  $\gamma 2$  subunit, this domain contains a consensus sequence for tyrosine-specific protein phosphorylation, suggesting a target for the cellular control of channel activity by receptor-mediated tyrosine kinases<sup>8</sup>. A putative control site for serine phosphorylation by protein kinase A is found within the same domain of the  $\beta 1$  subunit<sup>3</sup>. The overall sequence similarity to  $\alpha 1$  and  $\beta 1$  subunits is 42 and 35%, respectively. This level of structural similarity is seen for the different nicotinic acetylcholine receptor subunits<sup>9</sup> and is significantly below the 70–80% identity which typically characterizes the variants of GABA $_A$  receptor  $\alpha$ -subunits<sup>3,4</sup> or  $\beta$ -subunits (manuscript in preparation). Based on these structural considerations and the functional signature detailed below, the

$\gamma 2$  polypeptide is a novel GABA/benzodiazepine receptor subunit.

To determine the functional properties of the  $\gamma 2$  subunit, the cloned cDNA was transiently expressed in cultured human cells<sup>5</sup>, either singly or together with cloned cDNA encoding human  $\alpha 1$  and  $\beta 1$  subunits<sup>11</sup>. The membranes of the transfected cells were analysed for the binding of radiolabelled ligands specific for central benzodiazepine receptors<sup>2,10</sup>. High-affinity binding sites for [ $^3\text{H}$ ]Ro15-1788 ( $K_d = 1.2 \pm 0.2 \text{ nM}$ ,  $B_{\text{max}} = 2,900 \pm 300 \text{ fmol mg}^{-1}$ ; Fig. 2) and [ $^3\text{H}$ ]flunitrazepam ( $K_d \sim 2 \text{ nM}$ ,  $B_{\text{max}} \sim 2,000 \text{ fmol mg}^{-1}$ ; data not shown) were observed on cells expressing all three GABA $_A$  receptor subunits. The binding of these labelled compounds was completely blocked in the presence of  $1 \mu\text{M}$  diazepam ( $K_i = 10 \pm 2 \text{ nM}$ ), clonazepam ( $K_i = 1.1 \pm 0.7 \text{ nM}$ ) or methyl-4-ethyl-6,7-dimethoxy- $\beta$ -carboline-3-carboxylate (DMCM;  $K_i = 2.1 \pm 0.8 \text{ nM}$ ; data not shown). The  $K_i$  values of these compounds are similar to their rank order and potency determined on cerebellar membranes<sup>12</sup>. No

FIG. 3. Ionic and pharmacological characteristics of GABA-induced membrane currents in 293 cells expressing human GABA $_A$  receptor  $\alpha 1$ ,  $\beta 1$  and  $\gamma 2$  subunits. **a**, Current-voltage relation of GABA-induced responses (GABA,  $100 \mu\text{M}$ ). A reversal potential close to 0 mV was seen in  $126 \text{ mM} [\text{Cl}^-]_o$ . When  $[\text{Cl}^-]_o$  was lowered to  $40 \text{ mM}$  the reversal potential shifted to 30 mV, indicating a highly chloride-selective conductance. **b**, Flunitrazepam (FNZM,  $1 \mu\text{M}$ ) reversibly potentiated the GABA-induced current (GABA,  $5 \mu\text{M}$ ). This potentiation was completely inhibited by Ro15-1788 ( $1 \mu\text{M}$ ). DMCM ( $1 \mu\text{M}$ ) reduced the GABA-induced current by  $\sim 50\%$ . This reduction was lost in the presence of Ro15-1788 ( $1 \mu\text{M}$ ). **c**, Diazepam (DZP,  $1 \mu\text{M}$ ), FNZM ( $1 \mu\text{M}$ ) and pentobarbital (PB,  $50 \mu\text{M}$ ) all reversibly potentiated the current induced by  $10 \mu\text{M}$  GABA (// indicates a 5-min interval between subsequent applications).

**METHODS.** Membrane currents were recorded by the patch-clamp technique in the whole cell configuration<sup>13</sup>, using an EPC-7 patch-clamp amplifier (List Electronics, Darmstadt). Cells were clamped at  $-60 \text{ mV}$ . Data were filtered at 3 kHz (8-pole Bessel) and sampled up to 10 kHz. To determine the reversal potential of the transmitter-induced responses, membrane currents were measured while applying a voltage ramp ( $-120$  to  $120 \text{ mV}$ , 1.6 s duration). The current-voltage curves were calculated by subtracting currents ( $I$ ) before application of GABA from currents obtained in the presence of GABA, and were plotted as a function of membrane potential ( $V_m$ ). Substances were added, as indicated by bars, at the following concentrations: FNZM, DZP, Ro15-1788, and DMCM,

$1 \mu\text{M}$ ; PB,  $50 \mu\text{M}$ . Pipettes contained in mM: CsCl, 130; MgCl $_2$ , 1; CaCl $_2$ , 0.5; EGTA, 5; HEPES, 10; pH, 7.2. Cultures were continuously perfused with a solution containing in mM: KCl, 5.4; NaCl, 116; MgCl $_2$ , 0.8; CaCl $_2$ , 1.8; D-glucose, 11.1; NaHCO $_3$ , 26.2; HEPES, 5; pH, 7.2. All measurements were performed at room temperature.

binding was detected when the  $\gamma 2$  subunit alone or pairs of subunits were expressed. These data show that  $\alpha$ -,  $\beta$ - and  $\gamma$ -subunits can assemble into GABA<sub>A</sub> receptors which contain a high-affinity benzodiazepine binding site.

The receptors formed by co-expression of three different subunits were characterized by electrophysiology, using the whole cell patch-clamp technique<sup>13</sup> (Fig. 3). The application of GABA induced large inward currents; GABA sensitivity showed a Hill coefficient of  $\sim 1$ , as observed upon co-expression of  $\alpha$ - and  $\beta$ -subunits<sup>4</sup>. The selectivity for chloride ions is demonstrated by a shift in the current versus voltage curve when changing the concentration of extracellular chloride. The GABA-induced current was blocked by the GABA<sub>A</sub> receptor antagonist bicuculline ( $10^{-5}$  M) and the channel blocker picrotoxin ( $10^{-4}$  M) (data not shown) but was potentiated by the barbiturate pentobarbital. Importantly, these receptors display the full functional properties of GABA/benzodiazepine receptors. In all expressing cells tested, responses to GABA were consistently enhanced about

twofold by the benzodiazepine receptor agonists flunitrazepam and diazepam and reduced by 50% in the presence of the inverse agonist DMCM<sup>2,14</sup>. These effects were completely blocked by the benzodiazepine receptor antagonist Ro15-1788. This spectrum of sensitivity was not observed upon co-expressing  $\alpha 1\gamma 2$  and  $\beta 1\gamma 2$  subunit pairs. Furthermore, no responsiveness was seen on expression of the  $\gamma 2$  subunit alone which generated homomeric receptors (data not shown) comparable in their properties to the receptors formed from single  $\alpha$ - or  $\beta$ -subunits<sup>5</sup>. Our results indicate that all three subunits contribute to the formation of GABA/benzodiazepine receptors.

The  $\gamma 2$  subunit is comparable in abundance to  $\alpha$ - and  $\beta$ -subunits, as judged from the number of cognate cDNA clones in libraries of rat, bovine and human CNS origin and as evidenced by northern analysis of rat and bovine brain mRNA (unpublished observations). To determine the spatial pattern of  $\gamma 2$  mRNA expression in the CNS, we performed *in situ* hybridization on sagittal sections of rat brain, using as a probe a radioac-

FIG. 4 Location of neurons synthesizing  $\gamma 2$  subunit mRNA in rat brain. *In situ* hybridization was performed using a  $^{35}\text{S}$ -labelled cRNA on frozen, paraformaldehyde-fixed brain sections. Grain clusters in the emulsion mark the location of cells containing hybridizing mRNA in stained sections. Sections probed with  $^{35}\text{S}$ -labelled sense RNA produced no hybridization pattern (data not shown). *a*, Darkfield photomicrograph of cerebellar cortex (cb, left) and neocortex (cx, right). In cerebellar cortex,  $\gamma 2$  subunit mRNA expression is highest in the Purkinje neurons in the Purkinje cell layer (p) with an additional population of hybridizing cells (arrowheads) in the molecular layer (m) representing presumptive basket/stellate neurons. In the neocortex, numerous cells throughout layers II–VI express the  $\gamma 2$  subunit mRNA highly and display no obvious lamination pattern; neocortical layers I–III are shown. *b*, Bright-field photomicrograph of  $\gamma 2$  subunit mRNA expression in all Purkinje neurons (arrowheads). *c*, Dark-field photomicrograph of cerebellar cortex (left) and of the inferior colliculus (ic, right). Numerous cells expressing the  $\gamma 2$ -subunit mRNA are distributed throughout the inferior colliculus, unlike the superior colliculus (not shown). *d*, Dark-field photomicrograph of part of the hippocampal formation showing high  $\gamma 2$  subunit mRNA expression in granule neurons of the dentate gyrus (dg) and pyramidal neurons of the hippocampal CA3 and CA4 regions. CA1 and CA2 pyramidal neurons (not shown) similarly express  $\gamma 2$ -subunit mRNA. Scale bar in *a* (for *a*, *c* and *d*),

100  $\mu\text{m}$ ; in *b*, 30  $\mu\text{m}$ . Other abbreviations: *g*, granule cell layer; *w*, white matter.

**METHODS.** RNA probes were transcribed from a linearized Bluescript plasmid DNA, containing a 1,500-base pair *EcoRI* fragment from the coding region of rat  $\gamma 2$  cDNA. Following plasmid linearization at unique restriction sites in the polylinker region, sense or antisense RNA was synthesized using phage T3 or T7 RNA polymerase. RNA products were radiolabelled<sup>29</sup> to a specific activity of  $\sim 3 \times 10^8$  c.p.m.  $\mu\text{g}^{-1}$  using 1.0  $\mu\text{g}$  linearized plasmid DNA, 50  $\mu\text{Ci}$   $\alpha[^{35}\text{S}]\text{CTP}$  ( $1,000 \text{ Ci mmol}^{-1}$ , Amersham), 2.5 mM each of ATP, GTP and UTP, and were hydrolysed (pH 10, 37  $^{\circ}\text{C}$ , 1 h) to an average length of 100 nucleotides. For each section the RNA probe ( $2.5 \times 10^5$  c.p.m.) was dissolved in 50  $\mu\text{l}$  hybridization solution which included 0.6 M NaCl, 50% formamide, and 40 mM  $\beta$ -mercaptoethanol. *In situ* hybridization was performed as described previously<sup>30</sup>. Briefly, the sections were hybridized at 42  $^{\circ}\text{C}$  for 3 days, washed twice for 20 min each at 65  $^{\circ}\text{C}$  in  $0.1 \times \text{SSC}$ , 0.05% inorganic pyrophosphate, 14 mM  $\beta$ -mercaptoethanol, and dehydrated in alcohol. Following overnight exposure to Kodak XAR 5 film, the sections were dipped in Kodak NTB2 emulsion (diluted 1:1 in water), exposed for 8 days, and stained in 1% Fast Green and 0.5% cresyl violet. Sagittal brain structures were identified from ref. 31.

tively labelled cRNA derived from cloned rat  $\gamma 2$  cDNA (manuscript in preparation). Our results show that  $\gamma 2$  mRNA is prominently expressed in neuronal subsets throughout the CNS which include neurons in the olfactory bulb, anterior olfactory nuclei, preoptic area, neocortex, globus pallidus, hippocampus, dentate gyrus, thalamus, inferior colliculus, substantia nigra, pontine nuclei, cerebellar cortex and cerebellar nuclei. Four of these regions have been chosen to illustrate the cellular location of  $\gamma 2$  mRNA (Fig. 4). Significantly, all of these regions contain high-affinity binding sites for benzodiazepines<sup>15,16</sup> and also express  $\alpha$ - and  $\beta$ -subunit mRNAs (refs 17, 18; B.D.S., unpublished observations), further supporting the hypothesis that the  $\gamma 2$  subunit is an integral part of GABA/benzodiazepine receptors.

The existence of the  $\gamma 2$  subunit was not anticipated from biochemical studies as subunits of affinity-purified GABA/benzodiazepine receptor are electrophoretically resolved into only two main bands corresponding to relative molecular mass ( $M_r$ ) 48,000–53,000 (48K–53K) ( $\alpha$ ) and  $M_r$  55–57K ( $\beta$ ) (ref. 1). These bands, however, are heterogeneous, consisting of variants of the  $\alpha$ -subunits<sup>3,4</sup> and  $\beta$ -subunits, and of additional GABA<sub>A</sub> receptor subunits, including  $\gamma 2$  and a related  $\gamma 1$  subunit, whose cloning preceded that of  $\gamma 2$  and which shows glial localization (manuscript in preparation). The mature  $\gamma 2$ -polypeptide (unglycosylated,  $M_r \approx 48$ K) may co-migrate with  $\alpha$ -subunits ( $M_r$ , 48–53K)<sup>1,4</sup>, which have been postulated to carry the benzodiazepine site on the basis of photoaffinity labelling with flunitrazepam<sup>21–23</sup>. Our results on benzodiazepine responsiveness indicate that the  $\gamma$ -subunit contributes to the formation of the benzodiazepine site and thus may also be photoaffinity-labelled. In fact, it is probable that a flunitrazepam-labelled  $\gamma 2$  subunit would be indistinguishable from certain labelled  $\alpha$ -subunits by present methods.

We note that other subunit combinations may also create benzodiazepine responsiveness. Indeed, recent cDNA cloning experiments in our laboratory provide evidence for the existence of additional GABA<sub>A</sub> receptor subunits (manuscript in preparation). It seems likely therefore that the true diversity of GABA/benzodiazepine receptor subtypes has been only partly revealed by classical pharmacology<sup>12,19,20</sup>. □

CYSTICERCOSIS caused by larval tapeworms is a major public health problem and a cause of substantial economic losses in the farm-animal industries. *Taenia ovis* in sheep is a particularly important example. Immunity to reinfection with the larvae has a central role in regulating natural transmission of the parasites<sup>1</sup>, and vaccination with antigens from the early larval oncosphere stage can induce complete protection against infection<sup>2</sup>. As it is impractical to obtain enough oncospheres for a commercial vaccine against these tapeworms, an alternative approach is to use recombinant DNA methods to generate a cheap and plentiful supply of antigens. We report here the expression in *Escherichia coli* of complementary DNA encoding *T. ovis* antigens as fusion proteins with the *Schistosoma japonicum* glutathione S-transferase. Vaccination of sheep with these fusion proteins gave significant, although not complete, immunity against challenge infection with *T. ovis* eggs. Commercial development of a vaccine is being pursued.

Oncospheres of *T. ovis* were chosen as the source of messenger RNA for constructing a cDNA library because they are known to be a rich source of host-protective antigens<sup>3,4</sup>. Furthermore, *in vitro* culture techniques<sup>5</sup> have shown that hatched and activated *T. ovis* oncospheres secrete potent host-protective antigens<sup>6,7</sup>, suggesting synthesis is active. Oncospheres were therefore treated with artificial gastric and intestinal fluid and incubated before extraction of mRNA. To reduce the number of antigen-expressing cDNA clones to be tested in vaccination trials in sheep, it was first necessary to identify probable candidates for host-protective antigens. Preliminary experiments with sera from immune sheep showed strong antibody recognition of oncosphere antigens of relative molecular mass ( $M_r$ ) 47,000–52,000 (47–52K) (unpublished observations). The host-protective nature of the 47–52K antigens was demonstrated directly when lambs immunized with an SDS-PAGE cut-out of this region were protected significantly (98%) against challenge infection (Fig. 1). To isolate the genes encoding these antigens, rabbit antibodies specific for the 47–52K region were eluted from western blots and used to screen the expression library<sup>8</sup>. Figure 1 shows that the antibody probe was specific for the 47–52K region, and enabled us to isolate two clone types, designated 45S and 45W. Antigen- $\beta$ -galactosidase ( $\beta$ -gal) fusion proteins prepared from the clones ( $\beta$ -gal-45S and  $\beta$ -gal-45W) failed to stimulate host-protective immunity in sheep even though antibody was produced to the 47–52K antigens (Fig. 1). This experiment, however, demonstrated that the 47–52K region contains a series of serologically-related molecules, and that the antigens, or parts of them, had been cloned.

Plasmid vectors have been constructed recently which express antigens as fusion proteins with the enzyme glutathione S-transferase (GST) of *Schistosoma japonicum*, thereby enabling

<sup>†</sup> Present address: Department of Pathology, University of Cambridge, Tennis Court Road, Cambridge CB2 1QP, UK.

affinity-purification under non-denaturing conditions<sup>9</sup>. Fusion proteins GST-45S and GST-45W were prepared using a prototype of the vectors, pSj10Δ*Bam*7Stop7, and tested either separately or together in an immunization trial in lambs (Table 1, trial A). The results showed that GST-45W, either alone or in combination with GST-45S, stimulated significant host-protective immunity compared with the GST controls, whereas GST-45S alone was ineffective. The active component was therefore GST-45W, and a further vaccination trial was carried out using different adjuvants and doses of GST-45W. Significant levels of immunity were induced at all dose levels in oil, Freund's complete adjuvant or saponin adjuvants, the best being 94% protection with 50 μg GST-45W in saponin (Table 1, trial B).

FIG. 1 Immunoblotting analysis of *T. ovis* oncosphere antigens. Lanes probed with: pooled sera from five sheep before immunization (1); pooled sera from five sheep after immunization with an extract of 200,000 oncospheres solubilized in 2% SDS and 65 mM dithiothreitol (2); pooled sera from three sheep immunized with gel cut-out fraction (4); serum from a rabbit hyperimmunized with oncosphere extract (5); affinity-purified antibodies eluted from blots containing antigens with relative mobilities of 47–52K (6); pooled sera from three sheep immunized with  $\beta$ -gal (7); pooled sera from three sheep immunized with  $\beta$ -gal-45S (8); pooled sera from three sheep immunized with  $\beta$ -gal-45W (9); pooled sera from four sheep immunized with GST (10); pooled sera from four sheep immunized with GST-45S (11); pooled sera from four sheep immunized with GST-45W (12). Lane 3 shows oncosphere extract stained with silver<sup>16</sup> and the approximate size of gel cut-out injected into sheep is indicated between the arrows. Mean numbers of *T. ovis* cysticerci found in sheep injected with gel cut-out fraction, control polyacrylamide gel or whole oncosphere antigen in SDS plus gel were 1.0, 55.0 and 8.0, respectively. The sheep injected with the oncosphere gel cut-out were significantly ( $P < 0.01$ , 't' test) protected against infection.

**METHODS.** For vaccination, an extract from  $7 \times 10^6$  oncospheres was separated by SDS-PAGE through a 5–25% polyacrylamide gradient<sup>17</sup> and the fraction cut as shown. The fraction was homogenized with oil adjuvant<sup>15</sup> and injected part subcutaneously and part intramuscularly into three sheep on two occasions, 2 weeks apart. Positive control sheep were injected with homogenized polyacrylamide gel containing whole oncosphere antigen (three sheep) and negative control sheep were immunized with homogenized polyacrylamide gel without antigens (four sheep). Two weeks after the second injection sheep were infected with 5,000 viable *T. ovis* eggs and 6 weeks later carcasses were examined for cysts. For analysis, oncosphere antigens were separated by SDS-PAGE through 12–18% polyacrylamide gradients. Electrophoretic transfer to nitrocellulose<sup>18</sup> was followed by blocking for 2 h in 2% casein hydrolysate (Oxoid) 0.5% Tween 20 in 20 mM Tris-HCl buffer pH 7.4, containing 0.5 M NaCl (TBS). Sera were diluted 100-fold in 1% fish gelatin (Norland Products, USA) in TBS and incubated with blocked antigen strips overnight on a rocking platform. Strips were washed four times with TBS containing 0.05% Tween 20, and bound antibodies detected by incubation for 4 h with peroxidase-conjugated rabbit anti-sheep IgG (Cappel, Cooper Biomedical Inc.) or goat anti-rabbit IgG (Cappel) followed by washing and visualization with 4-chloro-1-naphthol (Biorad). Affinity-purified antibodies to the 47–52K antigens were prepared by elution of rabbit antibody from blots using 0.1 M glycine-HCl, pH 2.5 (ref. 8). Eluted antibodies were neutralized and fish gelatin carrier protein was added to 1% before concentration. The relative mobilities of standards are shown in the margins.

Although control sheep immunized with GST in saponin were not included in this trial, several experiments have since been carried out using saponin plus GST controls, with no non-specific protective effect being observed (unpublished observations).

Treatment of the fusion proteins with SDS and dithiothreitol substantially reduced protection (Table 1) indicating that the conformation of the fusion protein is important to its activity. Western blots of oncosphere antigen probed with sera from vaccinated sheep showed that antibody was directed predominantly against the 47–52K region (Fig. 1). The complete nucleotide sequence of the 928-base pair 45W cDNA is shown in Fig. 2. There is a single open reading frame in the sequence,

*T. ovis* eggs recovered from freshly purged tapeworms from dogs were washed thoroughly and stored at 4 °C for no more than 1 week. After hatching and activation<sup>15</sup>, the oncospheres were maintained *in vitro* for 2–3 h in DMEM, washed twice in sterile physiological saline, frozen and stored in liquid nitrogen. Approximately  $30 \times 10^5$  oncospheres were ground to a paste in liquid nitrogen and RNA isolated after solubilization in guanidine-HCl (ref. 10). Pooled total RNA (20–50 μg) was fractionated over oligo(dT) cellulose<sup>11</sup>. Polyadenylated RNA (400 ng) was transcribed into double-stranded cDNA using AMV reverse transcriptase and ribonuclease RNase H (Amersham cDNA synthesis system RPN.1256), methylated with *Eco*RI methylase (New England Biolabs) and ligated to *Eco*RI linkers (5'-GGAATTCC-3') (New England Biolabs). The cDNA was cloned<sup>12</sup> into  $\lambda$ gt11 yielding a library of  $7.5 \times 10^5$  individual recombinants. Fifty thousand phage plaques were screened<sup>12</sup> with affinity-purified anti-47–52K antibodies (Fig. 1) and five clones were identified, three of which were strongly immunoreactive and demonstrated to be siblings by direct sequencing. This clone type was designated  $\lambda$ gt11 45S. The other two clones were weakly immunoreactive and similarly grouped into a single class called  $\lambda$ gt11-45W. The inserts from the 45S and 45W  $\lambda$ gt11 clones were ligated into *Eco*RI-cleaved pSj10Δ*Bam*7Stop7 (ref. 9) and transformed into *E. coli* strain JM109 (ref. 14). Fusion proteins were prepared from these constructs, after transformation, by affinity chromatography on glutathione agarose<sup>9</sup> (Sigma) and stored at –70 °C before use in the vaccination trials. **Trial A.** The fusion proteins, oncosphere antigen, and GST control protein were emulsified in oil adjuvant<sup>15</sup> and injected subcutaneously into groups of four sheep on three occasions, 3 weeks apart. Total protein in the three doses of fusion protein amounted to 50 μg per sheep based on  $A_{280}$  estimation<sup>9</sup>. Solubilized oncosphere antigen equivalent to 150,000 oncospheres was injected in oil adjuvant in each positive control sheep. Three weeks after the third injection, all sheep were infected with ~5,000 viable *T. ovis* eggs and 6 weeks after infection, sheep carcasses were examined for cysts. **Trial B.** In the second trial sheep were immunized with three injections of GST-45W in oil adjuvant or with 1 mg Saponin HP2 (PPF) injected subcutaneously; or with Freund's complete adjuvant (FCA, Difco) intramuscularly on first injection, and with the second and third injections subcutaneously in incomplete adjuvant. Control positive sheep were immunized with oncosphere antigen as in Trial A. Two weeks after the third injection all sheep were infected with ~2,000 viable *T. ovis* eggs and 6 weeks after infection sheep carcasses were examined for cysts. The challenge infection with *T. ovis* eggs was deliberately decreased compared with trial A to mimic more closely a field infection. Despite the difference in challenge dose a similar per cent protection was observed in the GST-45W (oil adjuvant) groups of trials A and B.

— No protection relative to GST controls.

\* Significantly different from buffer and GST controls at  $P < 0.05$  ('t' test).

† Significantly different from buffer and GST controls at  $P < 0.01$  ('t' test).

FIG. 2 Nucleotide sequence and predicted amino-acid sequence of the 45W *EcoRI* cDNA. The DNA sequence of 928 nucleotides is numbered on the left starting at the *EcoRI* linker sequence and the TGA termination codon and putative polyadenylation signal, AATAAA, are indicated. The amino-acid sequence is given below the DNA sequence and its numbering is on the right. METHODS. The *EcoRI* fragment of  $\lambda$ gt11-45W containing *T. ovis* cDNA was cloned in both orientations into phage M13mp18 (ref. 19) for sequencing. Overlapping deletions of the cDNA insert cloned into M13mp18 were obtained by exonuclease III digestion as described by Henikoff<sup>20</sup>. Single-stranded DNA was prepared and both strands were sequenced by the dideoxy chain-termination method<sup>21</sup>.

maintaining the frame of both  $\lambda$ gt11 and pSj10 $\Delta$ Bam7Stop7. The predicted 25.83K peptide agrees with size estimates (26K) of the fusion protein on SDS-PAGE (data not shown), but differs substantially from the size of the native antigens, which may be post-translationally modified. The absence of a consensus translational start signal (ATG) indicated that the cDNA was not a complete copy of the 45W mRNA. Although the extent of the 5' end of the specific mRNA has not been determined, the potential upstream regions do not seem to be necessary for effective vaccination. Indeed, the protective epitope(s) may comprise only a small region of 45W; preliminary sequence data indicate that the non-protective, ~500-base pair 45S clone is a shorter version of 45W, so that further comparative analyses may allow definition of the host-protective epitope(s).

This report describes the first identification of a protective antigen of the taeniid cestodes produced by recombinant DNA methods. Although 100% protection was not achieved, the levels that were attained should enable a significant level of parasite control in the field and could form the basis of a commercial vaccine. □

‡ Department of Medicine, University of Birmingham & East Birmingham Hospital, B9 5ST, UK

INSULIN-dependent (type I) diabetes mellitus (IDDM) follows an autoimmune destruction of the insulin-producing  $\beta$ -cells of the pancreas<sup>1,2</sup>. Family and population studies indicate that predisposition is probably polygenic<sup>3</sup>. At least one susceptibility gene lies within the major histocompatibility complex and is closely linked to the genes encoding the class II antigens, HLA-DR and HLA-DQ (refs 3, 4). Fine mapping of susceptibility genes by linkage analysis in families is not feasible because of infrequent recombination (linkage disequilibrium) between the DR and DQ genes. Recombination events in the past, however, have occurred and generated distinct DR-DQ haplotypes, whose frequencies vary between races<sup>4-6</sup>. DNA sequencing and oligonucleotide dot-blot analysis of class II genes from two race-specific haplotypes indicate that susceptibility to IDDM is closely linked to the DQA1 locus and suggest that both the DQB1 (ref. 7) and DQA1 genes contribute to disease predisposition.

The polymorphic HLA-DQA1 and -DQB1 genes encode polypeptides that fold together to form a receptor that specifies T-lymphocyte recognition of self and foreign peptides<sup>8-13</sup>. DNA sequence analysis of DQ and DR genes from Caucasian patients with IDDM indicates that susceptibility to the disease correlates with the amino acid at position 57 of the DQ  $\beta$ -chain, with Asp at this position associated with resistance to IDDM<sup>7,14-16</sup>. An exception to this is that the 'Asp 57-negative' DQ  $\beta$ -chain encoded by DR3-DQw2 haplotypes, which are positively associated with IDDM, is also encoded by DR7-DQw2 haplotypes which are not increased in frequency in Caucasian patients<sup>3,7,17,18</sup>. This difference might arise because DR3 and DR7 haplotypes carry different DQA1 alleles<sup>7,18</sup>.

In black subjects, race-specific DR7 and DR9 haplotypes that are characterized by a unique TaqI restriction fragment-length polymorphism (RFLP) in DQB1, called DQBVIc, have been

TABLE 1 Major histocompatibility complex class II haplotypes and their associations with IDDM in blacks and Caucasians

Locus	DQB1	DQA1	DRB1	DRB4	DRA	Race	IDDM association
Alleles	DQw2	DR7-DQA1	<b>DR7</b>	<b>DRB4</b>	DR4	Caucasian	neutral
	DQw2	DR4-DQA1*	<b>DR7</b>	<b>DRB4</b>	DR4	black	positive
	DQw9	DR4-DQA1	<b>DR9</b>	<b>DRB3</b>	DR4	Caucasian	neutral
	DQw2*	DR4-DQA1	<b>DR9</b>	<b>DRB4</b>	DR4	black	positive

Major histocompatibility complex haplotypes referred to in the text are named according to their DR serological determinants, which correspond to their DRB1 polymorphism (shown in bold type). These haplotypes were determined by a combination of serological, RFLP and ASO dot-blot analysis<sup>6,7,23</sup>. Genes are given in the order in which they exist on chromosome 6.

\* Allelic substitutions that map susceptibility to IDDM to both the DQA1 and DQB1 genes.

TABLE 2 Frequencies of the DR4-DQA1 allele and DR7 haplotypes in black type 1 diabetic patients and control subjects

Specificity	IDDM patients (n=37) n (%)	Controls (n=79) n (%)	Relative risk	95% Confidence limits	P
DR7, DR4-DQA1	7 (18.9)	1 (1.3)	12.9	2.6-64.0	<0.005
DR7, DR7-DQA1	5 (13.5)	7 (8.9)	1.6	0.5-5.0	NS
DR4-DQA1	29 (78.4)	10 (12.7)	23	8.6-61.0	<10 <sup>-6</sup>

DR7, DR4-DQA1 and DR7, DR7-DQA1 refer to the number (%) of subjects with the DR7 antigen and the DR4-DQA1 and DR7-DQA1 alleles, respectively. The total numbers (%) of subjects with the DR4-DQA1 allele are given in the third row. The characteristics of the diabetic patients and control subjects, and the methods for DR serological typing for the RFLP studies and for the statistical analysis have been described previously<sup>6</sup>. All DR9- and DR7-positive control and patient subjects who possessed the DR4-DQA1 allele also possessed the DQBVIc RFLP. The two ASOs used to detect the DR4-DQA1 and DR7-DQA1 alleles were similar to two probes described previously<sup>23</sup>, and had the following sequences, respectively, 5'-TTCCGACAGATTTAGAAGATT-3' and 5'-TCTAAGTCTGTGGAACA-3'. Hybridization and washing conditions for dot blots were as previously described<sup>7</sup>, and washing temperatures were 59 °C and 50 °C for DR4-DQA1 and DR7-DQA1 ASOs, respectively. Using the previously described DQA1/DQA2-specific polymerase chain reaction (PCR) primers<sup>24</sup> and conditions recommended for Taq polymerase<sup>22</sup>, the signal from the dot blots was not satisfactory. Two per cent of the primary PCR product, obtained using the original DQA1/DQA2 primers<sup>24</sup>, was therefore subjected to a second round of Taq polymerase-catalysed amplification<sup>22</sup> using one of the original primers, GH26a (identical to GH26 (ref. 24), except that the restriction-site bases were not included) with a third oligonucleotide, DQA27B, 5'-GTAGAGTTGGAGCGTTA-3' (corresponding to codons 79-83 of the DQA1 gene). NS, Not significant.

described<sup>6</sup>. By contrast with the neutral effects of DR7 and DR9 in Caucasians<sup>3</sup>, both haplotypes are positively associated with IDDM<sup>6</sup>. In the present study, DNA sequences of the class II alleles present on these black haplotypes were analysed and compared with those from non-predisposing Caucasian DR7 and DR9 haplotypes, to identify any class II gene coding differences.

Genes *DRB1*, *DRB4*, *DQA1* and *DQB1* from a black patient, who was homozygous for DR7 and the DQBVIc RFLP, were cloned and sequenced. Analysis of the DNA sequences corresponding to the N-terminal domains of the DRβ1-, DRβ4- and DQB1-chains established that they were identical to those found on Caucasian DR7 haplotypes<sup>7,14,19,20</sup>. The only sequence difference detected was in the DQA1 allele. The black DQA1 allele was identical to the DQA1 allele found on Caucasian DR4 haplotypes (DR4-DQA1; Table 1)<sup>21</sup>.

The *DRB1*, *DRB4*, *DQA1* and *DQB1* alleles from a black patient homozygous for DR9 and the DQBVIc RFLP were also cloned and sequenced. The black DR9 haplotype contained the same *DQB1* allele (DQw2) as the black DR7 haplotype, in contrast to Caucasian DR9 haplotypes, which have the Asp 57-encoding DQw9 allele<sup>7</sup>. The predicted N-terminal amino-acid sequence encoded by the DQA1 allele was the same as that encoded by Caucasian DR9 and black DR7 haplotypes,

DR4-DQA1. The *DRB1* and *DRB4* alleles were identical to those on Caucasian DR9 haplotypes (Table 1)<sup>20</sup>.

To assess the contribution of the DR4-DQA1 allele to IDDM susceptibility, we used allele-specific oligonucleotide (ASO) dot-blot analysis<sup>7,22,23</sup>. Thirty-seven black patients with IDDM and 79 racially matched controls were tested (Table 2). Two ASOs were used, one that hybridizes to only the DR7-DQA1 allele, the other to the DR4-DQA1 allele (Table 2). The analysis revealed that all DR4-positive and DR9-positive patients and control subjects reacted positively with the DR4-DQA1 ASO, but were negative for the DR7-DQA1 ASO. Seven out of 11 DR7-positive patients were positive for the DR4-DQA1 ASO, compared with only 1 out of 8 DR7-positive controls (relative risk of IDDM, 12.9;  $P < 0.005$ ; Table 2). Conversely, 5 out of 11 DR7-positive patients reacted with the DR7-DQA1 ASO compared with 7 out of 8 DR7-positive controls (relative risk, 1.6, not statistically significant; Table 2). One patient, who was DR7-homozygous, was positive for both ASOs. Overall, the relative risk for the DR4-DQA1 allele was 23 (95% confidence limits 8.6-61.0;  $P < 10^{-6}$ ).

The identification of common DR polymorphisms in linkage disequilibrium with a rare combination of DQA1 and DQB1 alleles (Table 1) indicates that susceptibility to IDDM maps

FIG. 1 Arrangement of expressed major histocompatibility complex class II genes, HLA-DR and DQ, on chromosome 6.

centromeric to the DR subregion (Fig. 1). Substitution of the DR4-DQA1 allele for the DR7-DQA1 allele on black DR7 haplotypes correlates with a change in predisposition to IDDM from neutral to positive. Furthermore, substitution of the DQw2-DQB1 allele for the DQw9 allele on black DR9 haplotypes correlates with a change from neutral to positive. These findings indicate that a particular combination of DQA1 and DQB1 alleles is positively associated with IDDM. Although susceptibility may be influenced by other major histocompatibility complex genes, our data suggest that the conformation of the DQ molecules contributes to development of IDDM. □

## Two functionally different regions in Fos are required for the sequence-specific DNA interaction of the Fos/Jun protein complex

Manfred Neuberger, Marcus Schuermann, John B. Hunter & Rolf Müller

THE products of the cellular and retroviral *fos* genes associate with other nuclear proteins<sup>1,2</sup>, among them the transcription factor AP1/Jun (see ref. 3 for a review). The Fos/Jun complex binds to a specific symmetrical DNA recognition sequence<sup>3-9</sup> (termed TRE), thus stimulating transcription of the respective gene<sup>3,9-12</sup>. Here, we show that two distinct regions in Fos are required for the formation of a Fos/Jun/TRE complex. These are the leucine zipper<sup>13</sup>, involved in the association with Jun<sup>14</sup>, and a directly adjacent basic region. Specific amino-acid substitutions in this basic, presumably  $\alpha$ -helical, region abolish the interaction of Fos/Jun with the TRE but not the association of the two proteins. The functionally crucial amino acids are located in a region of Fos which is structurally similar to the putative DNA-binding sites in Jun and in the yeast transcriptional activator GCN4 (refs 15 and 16).

As a first step in investigating the role of Fos in the formation of a Fos/Jun/TRE complex we attempted to identify by site-directed mutagenesis those sequences in Fos that are crucial for complex formation. We concentrated this investigation on the

middle region of Fos, which evolutionarily is the most highly conserved<sup>17</sup> and is crucial for the induction of transformation<sup>18</sup> and transactivation<sup>10</sup>. Two long  $\alpha$ -helical regions are predicted in this region (amino acids 139-156 and 163-202)<sup>15</sup>. We generated Fos proteins that carried mutations in the putative second helix which forms a leucine zipper<sup>13</sup> with Jun<sup>14</sup> and various mutants altered in the first helix by exchanging single, pairs or triplets of basic amino acids either with other basic (Arg  $\rightarrow$  Lys; Lys  $\rightarrow$  Arg) or with neutral (Arg, Lys  $\rightarrow$  Gln) amino acids (Fig. 1). We also altered the non-polar sequence Met-Ala-Ala-Ala.

All mutants were analysed for ability to complex with Jun: <sup>35</sup>S-labelled, *in vitro*-translated Jun was incubated with unlabelled Fos, followed by immunoprecipitation with Fos-specific antibodies<sup>14</sup>. As previously shown<sup>14</sup>, binding was either reduced or abolished in several Fos proteins with a mutant leucine-repeat motif (for example, L2, FA183ins, L3-4-5). In contrast, alterations in the basic region did not affect binding to Jun (data not shown).

Next we analysed all mutant Fos proteins in a gel retardation assay using a synthetic oligonucleotide (termed ap1) containing a TRE. Figure 2 (upper panel, lanes 1-4) shows that in the assay conditions used, neither *in vitro*-translated Fos nor Jun shows any significant affinity for the ap1 oligonucleotide. But incubation of the two proteins before addition to the DNA results in a strong shift, indicating that Fos and Jun are binding cooperatively. The specificity of this interaction was demonstrated in competition experiments, in which a >1,000-fold increase in concentration of a random oligonucleotide compared with the specific ap1 oligonucleotide was necessary to abolish the band shift (data not shown). As expected, the ability of the leucine-repeat mutants (L3, L4, L2, L3-4-5, FA183ins) to form a stable Fos/Jun/DNA complex (Fig. 2) correlated well with their ability to associate with Jun<sup>14</sup>: the substitution of Leu 179 (L3), Leu 186 (L4) or Leu 172 (L2) either did not affect (L3) or it decreased (L4; L2) the Fos/Jun/DNA complex formation, whereas the triple leucine mutants L3-4-5 and the insertion mutant FA183ins, in which the orientation of leucine residues on one side of the helix is impaired, did not allow complex formation to any significant extent. These data indicate that the association of Fos and Jun through the leucine zipper is required for their interaction with the AP1 DNA-recognition sequence.

Gel retardation analysis of the other mutant Fos proteins revealed a second functionally unrelated domain in Fos that is involved in Fos/Jun/DNA complex formation. This domain is the basic, presumably  $\alpha$ -helical structure that is directly adjacent to the leucine repeat, as indicated by the reduced ability of mutant D9 and the failure of D3, D15, D19ins, D4 and D16 to

FIG. 1 Structure of the mutant Fos proteins and the parental E300 used in this study. Substituted amino acids are marked by double underlining. Numbers below the E300 sequence designate amino-acid positions in cellular and viral Fos proteins. The E300 Fos protein used in this study is a FBJ/FBR-MuSV hybrid, extending from amino acid 1-313 (ref. 14). The one-letter amino-acid code is used.

METHODS. Oligonucleotide-directed mutagenesis was by the gapped duplex DNA method based on pMa/5-8 and pMc/5-8 vector systems, as previously described<sup>14</sup>. Mutagenic oligonucleotides used were (numbers refer to nucleotide positions in FBR-MuSV<sup>25</sup>): D6: (2,369) 5'CTCTCGGATTGCT-GTTTCACTTGA (2,344); D8: (2,389) 5'GCAGCCAT-CTGATTCTGTTCTCTTCG (2,364); D9: (2,389) 5'GCAG-CCATCTGATTCCGTTCTC (2,368); D13: (2,380) 5'CT-TATTCGGTTCTTTTGTGATTCTCCG (2,353); D15: (2,399) 5'GGCACTTGGATGAAGACAGCTTATTCGTTG (2,369); D16: (2,410) 5'CTCCGATTCTTGACCTGGCTGCAGCC (2,383); D17: (2,421) 5'GTCAGCTCCTTCTTATTCCGGCAC (2,395); D19ins: (2,400)

FIG. 2 Gel retardation analysis of complex formation between Fos/Jun and the AP1 DNA-recognition sequence. *In vitro*-translated Fos and Jun proteins were allowed to form a complex as previously described<sup>14</sup> and then incubated with a <sup>32</sup>P-end-labelled double-stranded oligonucleotide (upper strand: 5'AAG-CATGAGTCAGACAC) containing an AP1 recognition sequence. DNA-protein complexes and uncomplexed oligonucleotides were separated on non-denaturing polyacrylamide gels. Protein-DNA complexes were formed in the absence of Fos (E300) or Jun proteins or after incubation of E300 or mutant E300 proteins with Jun. The structure of E300 mutants is shown in Fig. 1. METHODS. E300, *fos* mutants and *c-jun* complementary DNA<sup>26</sup> were transcribed *in vitro* and translated in reticulocyte lysate<sup>14</sup>. Binding reactions were performed by preincubating 5 µl Fos- and 5 µl Jun-containing *in vitro* translation mixtures with 1.5 µg ml<sup>-1</sup> poly(dI-dC) in buffer containing 10 mM HEPES, pH 7.9, 60 mM KCl, 4% Ficoll, 1 mM EDTA and 1 mM dithiothreitol for 60 min on ice. Two femtomoles of double-stranded oligonucleotide <sup>32</sup>P-labelled by polynucleotide kinase were added and incubation continued for 45 min at room temperature. The reaction mixtures were separated on 4% polyacrylamide gels at 10 V per cm<sup>27</sup>.

form a Fos/Jun/DNA complex (Fig. 2). Three aspects of these results deserve particular attention. First, there is no correlation between the elimination of positive charges and the impairment of binding. D6 and D8 (three and two basic amino acids replaced with glutamine, respectively) showed either no change or only a small reduction in their complex-forming potential. In contrast, the mutants having basic for basic amino-acid substitutions (D16) or an altered hydrophobic stretch (D15, D19ins) completely lost their complex-forming potential. Second, the results could indicate that specific interactions with DNA occur in this Fos domain. Although the alteration of certain pairs or triplets of amino acids (D6, D7) did not affect DNA complex-forming ability, the substitution of a single amino acid in D9 or the double mutation in D16 led to a reduction or the abrogation of DNA complex formation. Third, those sequences identified here as being crucial for the formation of a stable Fos/Jun/DNA complex are identical with those most highly conserved between Fos and Jun, namely the putative DNA-binding site in Jun<sup>16</sup> (Fig. 3).

Others have described a cooperative binding of Fos and Jun<sup>19,20</sup> and a crucial function for the leucine-repeat structure in Fos in the formation of a Fos/Jun/TRE complex<sup>21,22</sup>. In one study<sup>21</sup>, a single Fos construct containing a mutation outside the leucine repeat structure (Arg-Arg to Glu-Glu at positions 158-159) was found to have no complex-forming potential, a result differing from ours with mutant D17. This may implicate this region in DNA binding as the structures of both mutant proteins seem to be similar, according to structural predictions using two different algorithms<sup>23,24</sup>.

FIG. 3. Region of partial homology between the basic putative  $\alpha$ -helices in Fos and Jun. Vertical lines between Fos and Jun sequences indicate identical amino acids; functionally similar residues are depicted by dots. Amino acids that are conserved (+) or not conserved (-) in the basic regions of Fos, Jun and GCN4 are indicated below the sequences. The region in Fos containing amino acids crucial for DNA binding is marked by a line at the bottom of the figure.

On the basis of the available data, we propose a model in which Fos and Jun form a protein complex through the leucine zipper and each constituent interacts with one half-site of the palindromic DNA sequence. This hypothesis is in agreement with the symmetrical nature of the TRE: similar amino-acid sequences in Fos and Jun would interact with similar DNA sequences. The model is also supported by the observation that the DNA sequences directly flanking the TRE (5'...TGA<sup>c</sup>/GTC...') have no influence on the formation of a stable Fos/Jun/DNA complex (our unpublished results), practically excluding any sequence-specific interaction outside the AP1-recognition sequence. But as direct Fos protein-DNA contacts have been demonstrated by ultraviolet cross-linking experiments<sup>6</sup>, the TRE sequences seem to be the only possible site for a specific interaction of Fos with DNA. A final evaluation of the Fos/Jun/DNA complex will require further mutagenesis, footprint and ultraviolet cross-linking experiments. □

# The generation of mature T cells requires interaction of the $\alpha\beta$ T-cell receptor with major histocompatibility antigens

Bernadette Scott\*, Horst Blüthmann†, Hung Sia Teh\*‡ & Harald von Boehmer\*

\* Basel Institute for Immunology, 487 Grenzacherstrasse, CH 4056 Basel, Switzerland

† Central Research Units, Hoffman La-Roche & Co. Ltd, CH 4002 Basel, Switzerland

THE T-cell repertoire within an individual is biased to recognize antigen in the context of self major histocompatibility complex (MHC) antigens. This is thought to depend on a process of positive selection during development. Support for this notion has recently been obtained in experiments using transgenic mice bearing genes for T-cell receptors (TCR) of defined specificity: T cells expressing the introduced genes form the main part of the mature T-cell population only in mice that express the appropriate MHC product<sup>1,2</sup>. We have now extended these observations using TCR transgenic mice homozygous for the severe combined immunodeficiency (SCID) mutation which are defective in the rearrangement of both TCR and immunoglobulin genes. In this case mature thymocytes develop only in transgenic mice that express the MHC product which restricts the specificity of the transgenic TCR. This shows that the interaction of the  $\alpha\beta$  TCR with thymic MHC antigen is essential for the development of mature T cells. Furthermore, the peripheral lymph nodes of such mice are underdeveloped, suggesting that the peripheral expansion of mature T cells may require interactions with other lymphocytes expressing a range of receptors.

‡ Permanent address: Department of Microbiology, University of British Columbia, Vancouver, Canada V6T 1W5.

To produce mice which have only a very limited choice of TCRs we introduced the SCID mutation<sup>3</sup> into our  $\alpha\beta$  TCR transgenic mice. Mice homozygous for this mutation are grossly defective in productive rearrangements of immunoglobulin (Ig) and TCR genes<sup>4</sup>. We crossed the  $\alpha\beta$  TCR transgenic mouse line TG71<sup>5</sup> with C.B-17/Icr SCID mice and transgenic mice of the F<sub>1</sub> generation were further backcrossed to SCID mice. Mice were typed SCID/SCID by quantitating serum immunoglobulin levels. Because the TG71 line is H-2<sup>b</sup> and the C.B-17/Icr line is H-2<sup>d</sup> homozygous, H-2<sup>b/d</sup> heterozygous as well as H-2<sup>d</sup> homozygous  $\alpha\beta$ -transgenic SCID mice were obtained in the backcrosses. In initial experiments we compared the thymus of the SCID and transgenic SCID mice: the thymus of the former contained on average  $2 \times 10^6$  thymocytes whereas that of the latter contained more than  $5 \times 10^7$  thymocytes irrespective of the MHC haplotype. Although thymocytes from both types of mice were Thy-1-positive, only those of the transgenic SCID mice expressed CD4 and CD8 molecules (Fig. 1). (The weak staining of thymocytes from SCID mice with CD4 antibodies was probably due to nonspecific binding of this conjugate to CD4<sup>8</sup> lymphocytes because it was not observed with another CD4 antibody.) These results imply that the maturation of CD4<sup>8</sup> thymocytes from CD4<sup>8</sup> precursors<sup>6</sup> requires the productive rearrangement of TCR DNA segments. Crosses with mice expressing only the  $\alpha$ - or  $\beta$ -transgene are required to determine which TCR gene segments are necessary and sufficient for this step. These data indicate that the only defect of SCID mice is the defective rearrangement mechanism.
